Rockchip Confidencial

Revision 1.1
Nov. 2024

Copyright 2024 © Rockchip Electronics Co., Ltd.

Revision History

Date	Revision	Description
2024-11-22	1.1	Update the CRU, PMU, GRF, Mailbox, Audio Subsystem, ASRC, and SDMMC Chapters.
2024-09-02	1.0	Initial release

Table of Content

Table of Content 3
Figure Index 9
Table Index 13
Warranty Disclaimer 16
Chapter 1 System Overview 17
1.1 Address Mapping 17
1.2 System Boot 18
1.3 System Interrupt Connection 20
1.4 System DMA Hardware Request Connection 26
1.5 Rockchip Matrix IO Function List 27
Chapter 2 Clock & Reset Unit (CRU) 30
2.1 Overview 30
2.2 Block Diagram 30
2.3 Function Description 30
2.4 CRU Register Description 32
2.5 SCRU Register Description 96
2.6 CRU_PMU Register Description 102
2.7 SCRU PMU Register Description 126
2.8 Application Notes 126
Chapter 3 Cortex-A7 130
3.1 Overview 130
3.2 Block Diagram 130
3.3 Function Description 130
3.4 Register Description 130
Chapter 4 Cortex-M0 131
4.1 Overview 131
4.2 Block Diagram 131
4.3 Function Description 131
4.4 Register Description 132
4.5 Interface Description 133
4.6 Application Notes 134
Chapter 5 General Register Files (GRF) 139
5.1 Overview 139
5.2 Function Description 139
5.3 GRF Register Description 139
5.4 GRF_CORE Register Description 179
5.5 GRF_PMU Register Description 187
Chapter 6 Power Management Unit (PMU) 230
6.1 Overview 230
6.2 Block Diagram 230
6.3 Function Description 230
6.4 Register Description 233
6.5 Application Notes 267
Chapter 7 Internal SRAM 269
7.1 Overview 269
7.2 Block Diagram 269
7.3 Function Description 269
Chapter 8 DMA Controller (DMAC) 271
8.1 Overview 271

Rockchip Confidential

8.2 Block Diagram 272
8.3 Function Description 272
8.4 Register Description 273
8.5 Timing Diagram 329
8.6 Interface Description 329
8.7 Application Notes 330
Chapter 9 DMA2DDR 337
9.1 Overview 337
9.2 Architecture 337
9.3 Register description 338
9.4 Application Notes 355
Chapter 10 TIMER 356
10.1 Overview 356
10.2 Block Diagram 356
10.3 Function Description 356
10.4 Register Description 357
10.5 Application Notes 359
Chapter 11 HPTIMER 361
11.1 Overview 361
11.2 Block Diagram 361
11.3 Function Description 361
11.4 Register Description 362
11.5 Application Notes 369
Chapter 12 Watchdog Timer (WDT) 373
12.1 Overview 373
12.2 Block Diagram 373
12.3 Function Description 373
12.4 Register Description 374
Chapter 13 Mailbox 377
13.1 Overview 377
13.2 Block Diagram 377
13.3 Function Description 377
13.4 Register Description 378
13.5 Application Notes 381
Chapter 14 SARADC 382
14.1 Overview 382
14.2 Block Diagram 382
14.3 Function Description 382
14.4 Register Description 382
14.5 Application Notes 390
Chapter 15 Temperature-Sensor ADC (TSADC) 391
15.1 Overview 391
15.2 Block Diagram 391
15.3 Function Description 391
15.4 Register Description 391
15.5 Interface Description 398
15.6 Application Notes 398
Chapter 16 SPINLOCK 400
16.1 Overview 400
16.2 Block Diagram 400
16.3 Function Description 400

Rockchip Confidencial

16.4 Register Description 400
16.5 Application Notes 402
Chapter 17 GPIO 404
17.1 Overview 404
17.2 Block Diagram 404
17.3 Function Description 404
17.4 Register Description 407
17.5 Interface Description 418
17.6 Application Notes 422
Chapter 18 IO Controller (IOC) 423
18.1 Overview 423
18.2 Function Description 423
18.3 GPIO0_IOC Register Description 423
18.4 GPIO1_IOC Register Description 450
18.5 GPIO2_IOC Register Description 482
18.6 GPIO3_IOC Register Description 501
18.7 GPIO4_IOC Register Description 517
18.8 Application Notes 518
Chapter 19 Rockchip Matrix IO 520
19.1 Overview 520
19.2 Block Diagram 520
19.3 Function Description 520
19.4 Register Description 521
19.5 Interface Description 587
19.6 Application Notes 588
Chapter 20 Audio Subsystem 589
20.1 Overview 589
20.2 Block Diagram 589
20.3 Function Description 589
Chapter 21 Audio DSM 592
21.1 Overview 592
21.2 Block Diagram 592
21.3 Function description 593
21.4 Register Description 593
21.5 Interface Description 605
21.6 Application Notes 605
Chapter 22 Audio ADC 607
22.1 Overview 607
22.2 Block Diagram 607
22.3 Function Description 608
22.4 Register Description 611
22.5 Application Notes 627
Chapter 23 Serial Audio Interface (SAI) 628
23.1 Overview 628
23.2 Block Diagram 628
23.3 Function Description 629
23.4 Register Description 631
23.5 Interface Description 643
23.6 Application Notes 646
Chapter 24 Pulse Density Modulation (PDM) 647
24.1 Overview 647

24.2 Block Diagram 647
24.3 Function Description 648
24.4 Register Description 649
24.5 Interface Description 657
24.6 Application Notes 658
Chapter 25 SPDIF TX 659
25.1 Overview 659
25.2 Block Diagram 659
25.3 Function Description 660
25.4 Register Description 661
25.5 Interface Description 667
25.6 Application Notes 668
Chapter 26 SPDIF RX 669
26.1 Overview 669
26.2 Block Diagram 669
26.3 Function description 670
26.4 Register Description 672
26.5 Interface Description 680
26.6 Application Notes 681
Chapter 27 Asynchronous Sample Rate Converter (ASRC) 682
27.1 Overview 682
27.2 Block Diagram 682
27.3 Function Description 683
27.4 Register Description 686
27.5 Application Notes 697
Chapter 28 Flexible Serial Peripheral Interface（FSPI） 700
28.1 Overview 700
28.2 Block Diagram 700
28.3 Function Description 701
28.4 Register Description 701
28.5 Interface Description 724
28.6 Application Notes 725
Chapter 29 Serial Peripheral Interface (SPI) 729
29.1 Overview 729
29.2 Block Diagram 729
29.3 Function Description 731
29.4 Register Description 732
29.5 Interface Description 741
29.6 Application Notes 742
Chapter 30 SPI2APB 745
30.1 Overview 745
30.2 Block Diagram 745
30.3 Function Description 745
30.4 Register Description 748
30.5 Interface Description 750
30.6 Application Notes 750
Chapter 31 Pulse Width Modulation (PWM) 751
31.1 Overview 751
31.2 Block Diagram 752
31.3 Function Description 752
31.4 Register Description 754
31.5 Interface Description 782

Rockchip Confidential

31.6 Application Notes 782
Chapter 32 Inter-Integrated Circuit (I2C) 786
32.1 Overview 786
32.2 Block Diagram 786
32.3 Function Description 787
32.4 Register Description 789
32.5 Interface Description 798
32.6 Application Notes 799
Chapter 33 Universal Asynchronous Receiver/Transmitter 802
33.1 Overview 802
33.2 Block Diagram 802
33.3 Function Description 803
33.4 Register Description 805
33.5 Interface Description 825
33.6 Application Notes 827
Chapter 34 Controller Area Network (CAN) 830
34.1 Overview 830
34.2 Function Description 830
34.3 Register Description 837
34.4 Interface Description 864
34.5 Application Notes 864
Chapter 35 Master Double Data Rate Serial Memory Controller (MASTER DSMC) ... 867
35.1 Overview 867
35.2 Block Diagram 867
35.3 Function Description 868
35.4 Register Description 871
35.5 Interface Description 885
35.6 Application Notes 886
Chapter 36 Slave Double Date Rate Serial Memory Controller (SLAVE DSMC) 889
36.1 Overview 889
36.2 Block Diagram 889
36.3 Function Description 890
36.4 Register Description 891
36.5 Common Register Description 900
36.6 Interface Description 905
36.7 Application Notes 905
Chapter 37 Flexible Bus (FlexBUS) 906
37.1 Overview 906
37.2 Block Diagram 907
37.3 Function Description 907
37.4 Register Description 912
37.5 Interface Description 928
37.6 Application Notes 930
Chapter 38 MAC Ethernet Interface (MAC) 933
38.1 Overview 933
38.2 Block Diagram 936
38.3 Function Description 937
38.4 Register Description 941
38.5 Interface Description 1051
38.6 Application Note 1052
Chapter 39 Mobile Storage Host Controller (SDMMC&EMMC) 1078

SDMMC	0xFF480000	32KB	Secure KEYLAD	0xFFFD0000	64KB
FSPI	0xFF488000	32KB	Secure RNG	0xFFFE0000	64KB
SAI2	0xFF498000	32KB	BOOTROM	0xFFFF0000	24KB
SAI3	0xFF4A0000	32KB			

The following table shows the BootROM /System SRAM address before and after remapping. Before remapping, 0xFFF80000 and 0xFFFF0000 is the base address for System SRAM and BootROM separately. After remapping, BootROM could not be accessed, both 0xFFFF80000 and 0xFFFF0000 are the base address for System SRAM and only 64KB System SRAM space could be accessed from 0xFFFF0000 base address.

Table 1-2 RK3506 BootROM /System SRAM Remap Function

Before remap		After remap	
0xFFF80000	System SRAM(48K)	0xFFF80000/0xFFFF0000	System SRAM(48K)
0xFFFF0000	BootROM(24K)	Not Access	BootROM(24K)

The following table shows the DDR /DSMC_MEM address before and after remapping. Before remapping, 0x00000000 and 0xC00000000 is the base address for DDR and DSMC_MEM separately. After remapping, DDR could not be accessed, 0x00000000 is the base address for DSMC_MEM.

Table 1-3 RK3506 DDR /DSMC_MEM Remap Function

Before remap		After remap	
0xC0000000	DSMC_MEM(1008M)	0x00000000	DSMC_MEM(1008M
0x00000000	DDR(3072M)	Not Access	DDR(3072M)

1.2 System Boot

RK3506 provides system boot from off-chip devices such as eMMC memory, Serial NAND or NOR Flash, SDMMC card. When boot code is not ready in these devices, the boot code can be programmed through USB2.0 OTG interface or SPI2 interface by running ROM code in BootROM. All of the ROM code is hard code in internal BootROM. Below figure shows the procedure of ROM code execution.

The following features are supported by ROM code.

- Support system boot from the following device:
  - eMMC Interface, 4bits data width
  - Serial NOR Flash, 1/4bits data width
  - SDMMC Card, 4bits data width
- Support system code download by USB2.0 OTG0
- Support system code download by SPI2

Following figure shows typical RK3506 boot procedure flow. Boot sequence can be adjusted by changing SARADC_IN0 voltage level.

1.3 System Interrupt Connection

RK3506 provides a general interrupt controller (GIC) for CPU, which has 154 SPI (shared peripheral interrupts) interrupt sources and 6 PPI (Private peripheral interrupt) interrupt sources. The triggered type for each SPI interrupt is high level sensitive, and for each PPI interrupt is low level sensitive, both are not programmable. The detailed interrupt sources connection is in the following table.

Table 1-4 RK3506 Interrupt Connection List

Interrupt Type	Interrupt ID	Source	Polarity
PPI	N/A	16	Low level
	N/A	17	Low level
	N/A	18	Low level
	N/A	19	Low level
	N/A	20	Low level

1.4 System DMA Hardware Request Connection

RK3506 provides two DMAC in the system. The handshake channel number between peripheral and DMAC is described in this section. For detailed descriptions of DMAC, please refer to DMAC Chapter.

Some DMAC channels may receive multiple peripheral requests but can only receive one at the same time. For detailed configuration, please refer to GRF Chapter.

1.5 Rockchip Matrix IO Function List

RK3506 support one Rockchip Matrix IO (RM_IO) which are designed to let numerous functional signals share limited pin interfaces. Within the same matrix, any function signal can be mapped to any pin interface by software configurable.
RM_IO support 98 function signals map to 32 pin interfaces (GPIO0_A0~GPIO0_C7, GPIO1_B1, GPIO1_B2, GPIO1_B3, GPIO1_C2, GPIO1_C3, GPIO1_D1, GPIO1_D2, GPIO1_D3).

Chapter 2 Clock & Reset Unit (CRU)

2.1 Overview

CRU is an APB slave module that is designed for generating all kinds of internal and system clocks and resets in the chip. CRU generates system clocks from PLL output clock or external clock source, and generates system reset from external power-on-reset, watchdog timer reset, software reset or temperature sensor.
We design a sub module called CRU_PMU inside CRU. Both CRU and CRU_PMU APB slave address space are 64KB, we define higher 32KB as secure address space.
The CRU supports the following features:

- Compliance with AMBA APB interface
- Embedded with 3 fractional PLLs (GPLL, V0PLL and V1PLL)
- Flexible selection of clock source
- Use clock matrix scheme
- Support dividing clock separately
- Support gating clock separately
- Support software reset each module separately

2.2 Block Diagram

The CRU comprises with:

- PLL
- Register configuration unit
- Clock generate unit
- Reset generate unit

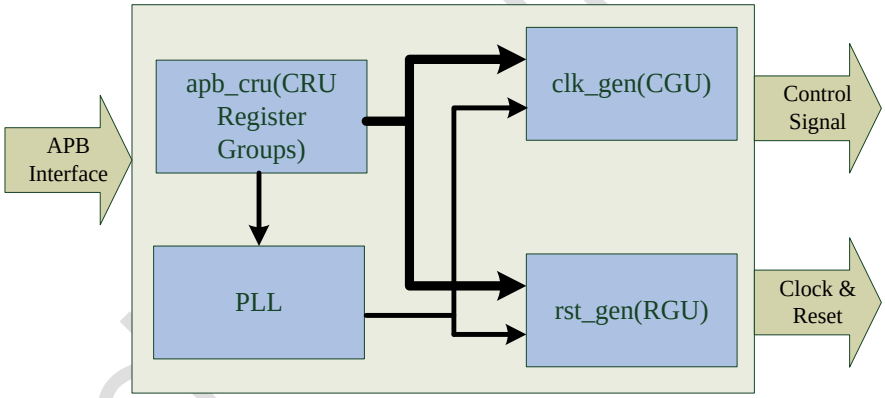

Fig. 2-1 CRU Block Diagram

2.3 Function Description

2.3.1 PLL Introduction

The PLL is a general purpose, high-performance PLL-based clock generator. Also, the PLL is a multi-function, general purpose frequency synthesizer. Ultra-wide input and output ranges along with best-in-class jitter performance allow the PLL to be used for almost any clocking application. With excellent supply noise immunity, the PLL is ideal for use in noisy mixed signal SoC environments. The main features of PLL are as following table.

Table 2-1 PLL Main Features

	FRACPLL(INT Mode)		FRACPLL(FRAC Mode)	
Parameter	Min	Max	Min	Max
FREF(MHz)	1	1200	10	1200M
REFDIV	1	63	1	63
FBDIV	16	3800	20	380
POSTDIV1	1	7	1	7

Rockchip Confidencial

POSTDIV2	1	7	1	7
PFD(MHz)	1	FOUTVCO/16	1	FOUTVCO /20
FOUTVCO(MHz)	950	3800	950	3800
FOUTPOSTDIV(MHz)	19	3800	19	3800
lock time(us)		500*REFDIV/FREF		500*REFDIV/FREF

PLL block diagram is shown below:

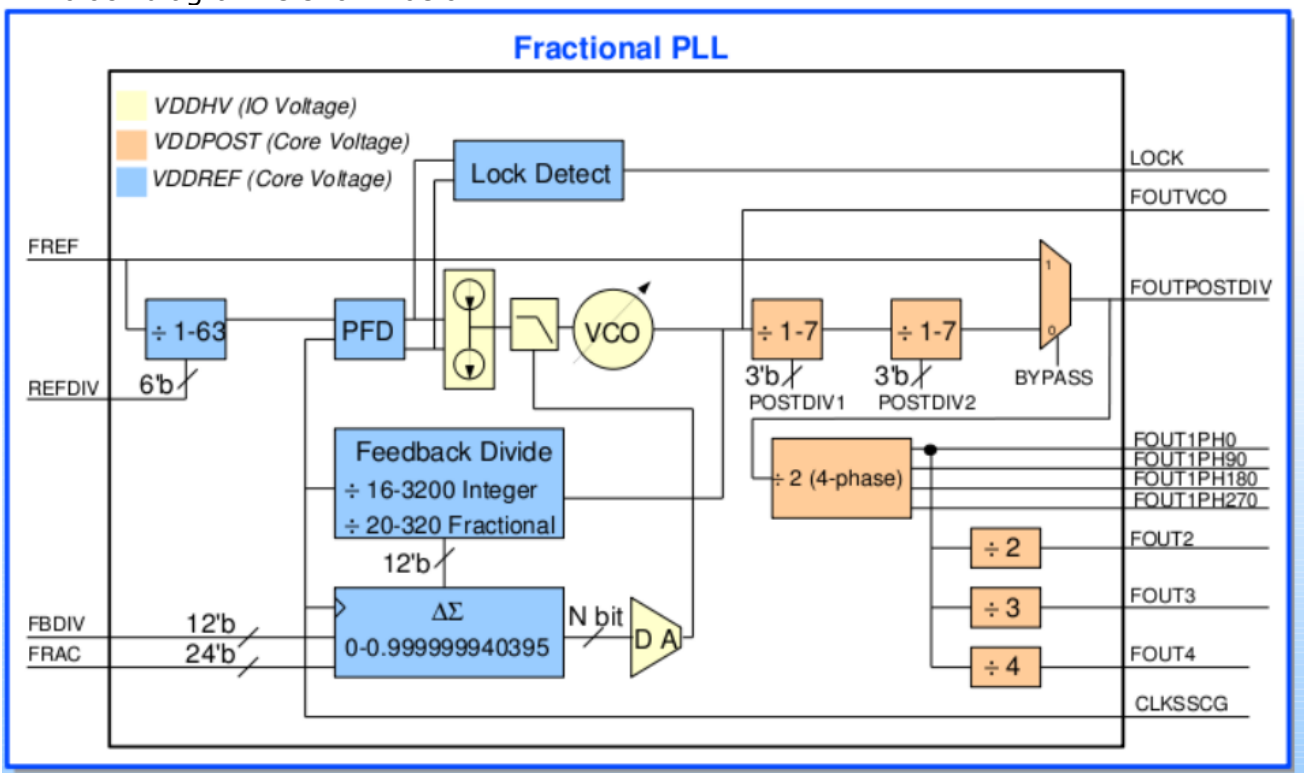

Fig. 2-2 PLL Block Diagram

2.3.2 System Clock Solution

There are 3 fractional PLLs in RK3506: GPLL, V0PLL and V1PLL. All PLLs can receive 24MHz oscillator as input reference clock. In addition, V0PLL and V1PLL supports reference clock from GPIO.

ALL PLLs can be set to three work modes: normal mode, slow mode and deep slow mode. Before power on or changing PLL setting, we must program PLL into slow mode or deep slow mode. To maximize the flexibility, some clocks can select divider source from multiple PLLs. To provide some specific frequency, another solution is integrated: fractional divider and Divfree50 divider are also provided for some modules. All clocks can be gated by software.

The basic units for clock generation are:

- Gating
- MUX (multiplexer)
- Divfree(Glitch free divider)
  - clk_out_freq= clk_in_freq/(divcon + 1)
  - When divcon is even, the clock duty cycle of clk_out is 50%
  - When divcon is odd, the clock duty cycle of clk_out is not 50%
- Fracdiv(Fractional divider)
  - clk_out_freq= clk_in_freq*numerator/denominator, both numerator and denominator are 16 bits
- Divfree50(Glitch free divider for duty cycle 50%)
  - clk_out_freq= clk_in_freq/(divcon +1)
  - When divcon is even or odd, the clock duty cycle of clk_out is 50%

The settings of all basic units are controlled by CRU registers.

Rockchip

2.3.3 System Reset Solution

Almost all modules have these reset source as the following figure shows. The 'xxx' in the figure is the module name.

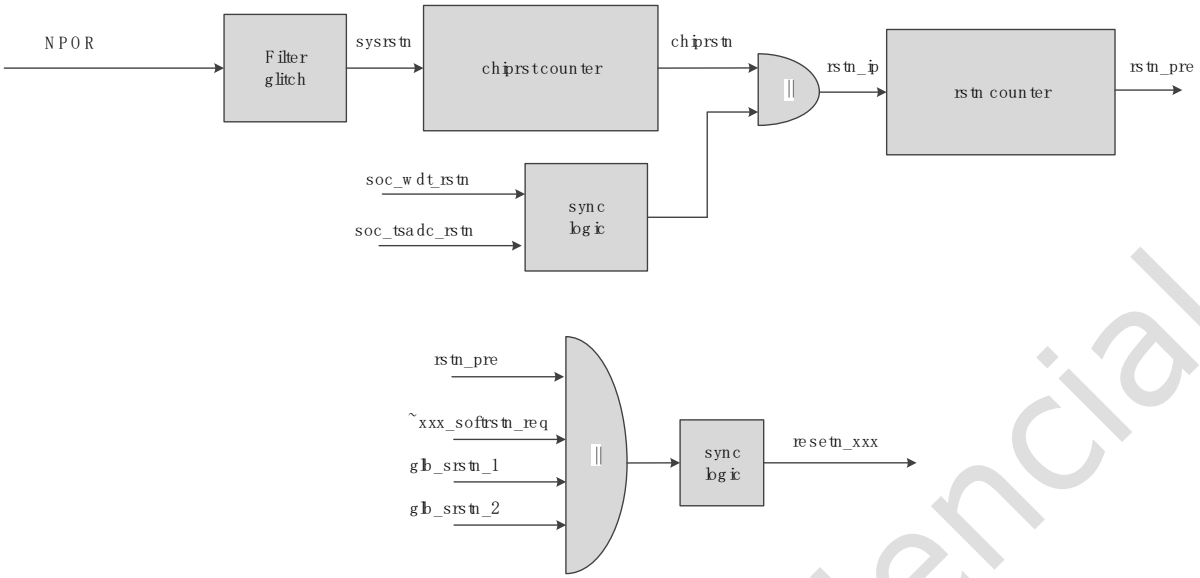

Fig. 2-3 Reset Architecture Diagram

Reset source of each reset signal includes:

- nPOR: External power on reset
- soc_wdt_rstn: Reset from WDT module
- soc_tsadc_rstn: Reset from TSADC module
- softrstn_req: Software reset request by programming CRU_SOFTRST_CON
- glb_srstn_1: First global software reset by programming CRU_GLB_SRST_FST as 0xfdb9
- glb_srstn_2: Second global software reset by programming CRU_GLB_SRST_SND as 0xeca8

2.4.2 Detail Registers Description

CRU_MODE_CON00

Address: Operational Base(0xFF9A0000) + offset (0x0280)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:6	RO	0x000	reserved
5:4	RW	0x0	clk_v1pll_mode clk_v1pll_mux clock mux. 2'b00: xin_osc0_func 2'b01: clk_v1pll 2'b10: clk_deepslow
3:2	RW	0x0	clk_v0pll_mode clk_v0pll_mux clock mux. 2'b00: xin_osc0_func 2'b01: clk_v0pll 2'b10: clk_deepslow

Rockchip Confidential

Bit	Attr	Reset Value	Description
1:0	RW	0x0	clk_gpll_mode clk_gpll_mux clock mux. 2'b00: xin_osc0_func 2'b01: clk_gpll 2'b10: clk_deepslow

CRU_CLKSEL_CON00

Address: Operational Base(0xFF9A0000) + offset (0x0300)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:14	RO	0x0	reserved
13:10	RW	0x1	clk_gpll_div_100m_div Divide clk_gpll_div_100m by (div_con + 1).
9:6	RW	0x3	clk_gpll_div_div Divide clk_gpll_div by (div_con + 1).
5:0	RO	0x00	reserved

CRU_CLKSEL_CON01

Address: Operational Base(0xFF9A0000) + offset (0x0304)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:13	RO	0x0	reserved
12:8	RW	0x0b	clk_int_voice_matrix0_div DT50 division register. Divide clk_int_voice_matrix0 by (div_con + 1).
7:4	RW	0x6	clk_v1pll_div_div Divide clk_v1pll_div by (div_con + 1).
3:0	RW	0x7	clk_v0pll_div_div Divide clk_v0pll_div by (div_con + 1).

CRU_CLKSEL_CON02

Address: Operational Base(0xFF9A0000) + offset (0x0308)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:10	RO	0x00	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
9:5	RW	0x11	clk_int_voice_matrix2_div DT50 division register. Divide clk_int_voice_matrix2 by (div_con + 1).
4:0	RW	0x09	clk_int_voice_matrix1_div DT50 division register. Divide clk_int_voice_matrix1 by (div_con + 1).

CRU_CLKSEL_CON03

Address: Operational Base(0xFF9A0000) + offset (0x030C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15	RO	0x0	reserved
14:13	RW	0x1	clk_frac_voice_matrix0_mux_sel clk_frac_voice_matrix0_mux clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
12:11	RW	0x1	clk_frac_uart_matrix1_mux_sel clk_frac_uart_matrix1_mux clock mux. 2'b00: xin_osc0_func 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
10:9	RW	0x1	clk_frac_uart_matrix0_mux_sel clk_frac_uart_matrix0_mux clock mux. 2'b00: xin_osc0_func 2'b01: clk_gpll_mux 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
8:5	RW	0x0	clk_testout_sel clk_testout clock mux. 4'b0000: xin_osc0_func_gate 4'b0001: clk_gpll 4'b0010: clk_v0pll 4'b0011: clk_v1pll 4'b0100: clk_deepslow 4'b0101: clk_rc 4'b0110: clk_core_pvtpll_logic 4'b0111: clk_frac_uart_matrix0 4'b1000: clk_frac_voice_matrix0 4'b1001: clk_core_src_pre

Rockchip Confidencial

Bit	Attr	Reset Value	Description
			4'b1010: clk_usbotg0_utmi_phy 4'b1011: clk_usbotg1_utmi_phy 4'b1100: dsi_lanebyte_clk_phy 4'b1101: dsi_rxclk_esc_phy 4'b1110: clk_spdifrx_to_asrc 4'b1111: Reserved
4:0	RW	0x00	clk_testout_div Divide clk_testout by (div_con + 1).

CRU_CLKSEL_CON04

Address: Operational Base(0xFF9A0000) + offset (0x0310)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:8	RO	0x00	reserved
7:6	RW	0x1	clk_frac_common_matrix2_mux_sel clk_frac_common_matrix2_mux clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
5:4	RW	0x1	clk_frac_common_matrix1_mux_sel clk_frac_common_matrix1_mux clock mux. 2'b00: xin_osc0_func 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
3:2	RW	0x1	clk_frac_common_matrix0_mux_sel clk_frac_common_matrix0_mux clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
1:0	RW	0x1	clk_frac_voice_matrix1_mux_sel clk_frac_voice_matrix1_mux clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate

CRU_CLKSEL_CON05

Address: Operational Base(0xFF9A0000) + offset (0x0314)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:0	RW	0x00060019	clk_frac_uart_matrix0_div clk_frac_uart_matrix0 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON06

Address: Operational Base(0xFF9A0000) + offset (0x0318)

Bit	Attr	Reset Value	Description
31:0	RW	0x01200c35	clk_frac_uart_matrix1_div clk_frac_uart_matrix1 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON07

Address: Operational Base(0xFF9A0000) + offset (0x031C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00c00c35	clk_frac_voice_matrix0_div clk_frac_voice_matrix0 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON08

Address: Operational Base(0xFF9A0000) + offset (0x0320)

Bit	Attr	Reset Value	Description
31:0	RW	0x000000	clk_frac_voice_matrix0_div_high clk_frac_voice_matrix0 fraction division high bits register. bit23-16 for the bit23~16 of numerator bit7-0 for the bit23~16 of denominator

CRU_CLKSEL_CON09

Address: Operational Base(0xFF9A0000) + offset (0x0324)

Bit	Attr	Reset Value	Description
31:0	RW	0x03723d09	clk_frac_voice_matrix1_div clk_frac_voice_matrix1 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON10

Address: Operational Base(0xFF9A0000) + offset (0x0328)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	clk_frac_voice_matrix1_div_high clk_frac_voice_matrix1 fraction division high bits register. bit23-16 for the bit23~16 of numerator bit7-0 for the bit23~16 of denominator

Rockchip Confidencial

CRU_CLKSEL_CON11

Address: Operational Base(0xFF9A0000) + offset (0x032C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00800c35	clk_frac_common_matrix0_div clk_frac_common_matrix0 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON12

Address: Operational Base(0xFF9A0000) + offset (0x0330)

Bit	Attr	Reset Value	Description
31:0	RW	0x00070064	clk_frac_common_matrix1_div clk_frac_common_matrix1 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON13

Address: Operational Base(0xFF9A0000) + offset (0x0334)

Bit	Attr	Reset Value	Description
31:0	RW	0x01290c80	clk_frac_common_matrix2_div clk_frac_common_matrix2 fraction division register. High 16-bit for numerator Low 16-bit for denominator

CRU_CLKSEL_CON15

Address: Operational Base(0xFF9A0000) + offset (0x033C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:13	RO	0x0	reserved
12:9	RW	0x1	aclk_core_root_div Divide aclk_core_root by (div_con + 1).
8	RW	0x0	clk_core_src_pvtmux_sel clk_core_src_pvtmux clock mux. 1'b0: clk_core_src_pre 1'b1: clk_core_pvtpll_src
7	RW	0x0	clk_core_pvtpll_src_sel clk_core_pvtpll_src clock mux. 1'b0: clk_deepslow 1'b1: clk_core_pvtpll

Rockchip Confidential

Bit	Attr	Reset Value	Description
6:5	RW	0x2	clk_core_src_div_sel clk_core_src_div clock mux. 2'b00: clk_gpll_mux_gate 2'b01: clk_v0pll_mux_gate 2'b10: clk_v1pll_mux_gate
4:0	RW	0x00	clk_core_src_div_div Divide clk_core_src_div by (div_con + 1).

CRU_CLKSEL_CON16

Address: Operational Base(0xFF9A0000) + offset (0x0340)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:4	RO	0x000	reserved
3:0	RW	0x7	pclk_core_root_div Divide pclk_core_root by (div_con + 1).

CRU_CLKSEL_CON18

Address: Operational Base(0xFF9A0000) + offset (0x0348)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:14	RO	0x0	reserved
13:12	RW	0x2	clk_dsmc_sel clk_dsmc clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
11:7	RW	0x03	clk_dsmc_div DT50 division register. Divide clk_dsmc by (div_con + 1).
6:5	RW	0x0	aclk_core_peri_root_sel aclk_core_peri_root clock mux. 2'b00: clk_gpll_mux_gate 2'b01: clk_v0pll_mux_gate 2'b10: clk_v1pll_mux_gate
4:0	RW	0x02	aclk_core_peri_root_div Divide aclk_core_peri_root by (div_con + 1).

CRU_CLKSEL_CON19

Rockchip Confidential

Address: Operational Base(0xFF9A0000) + offset (0x034C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:14	RO	0x0	reserved
13:12	RW	0x1	clk_flexbus_rx_sel clk_flexbus_rx clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
11:7	RW	0x03	clk_flexbus_rx_div DT50 division register. Divide clk_flexbus_rx by (div_con + 1).
6:5	RW	0x1	clk_flexbus_tx_sel clk_flexbus_tx clock mux. 2'b00: xin_osc0_func_gate 2'b01: clk_gpll_mux_gate 2'b10: clk_v0pll_mux_gate 2'b11: clk_v1pll_mux_gate
4:0	RW	0x03	clk_flexbus_tx_div DT50 division register. Divide clk_flexbus_tx by (div_con + 1).

CRU_CLKSEL_CON21

Address: Operational Base(0xFF9A0000) + offset (0x0354)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:14	RO	0x0	reserved
13:12	RW	0x1	hclk_bus_root_sel hclk_bus_root clock mux. 2'b00: clk_gpll_div 2'b01: clk_v0pll_div 2'b10: clk_v1pll_div
11:7	RW	0x00	hclk_bus_root_div Divide hclk_bus_root by (div_con + 1).
6:5	RW	0x0	aclk_bus_root_sel aclk_bus_root clock mux. 2'b00: clk_gpll_div 2'b01: clk_v0pll_div 2'b10: clk_v1pll_div

Rockchip Confidencial

Bit	Attr	Reset Value	Description
4:0	RW	0x00	aclk_bus_root_div Divide aclk_bus_root by (div_con + 1).

CRU_CLKSEL_CON22

Address: Operational Base(0xFF9A0000) + offset (0x0358)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:13	RW	0x0	clk_timer0_ch2_sel clk_timer0_ch2 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_div_100m 3'b010: clk_deepslow 3'b011: clk_core_pvtpll_logic 3'b100: sai2_mclk_io_in 3'b101: sai2_sclk_io_in
12:10	RW	0x0	clk_timer0_ch1_sel clk_timer0_ch1 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_div_100m 3'b010: clk_deepslow 3'b011: clk_core_pvtpll_logic 3'b100: sai1_mclk_io_in 3'b101: sai1_sclk_io_in
9:7	RW	0x0	clk_timer0_ch0_sel clk_timer0_ch0 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_div_100m 3'b010: clk_deepslow 3'b011: clk_core_pvtpll_logic 3'b100: sai0_mclk_io_in 3'b101: sai0_sclk_io_in
6:5	RW	0x0	pclk_bus_root_sel pclk_bus_root clock mux. 2'b00: clk_gpll_div 2'b01: clk_v0pll_div 2'b10: clk_v1pll_div
4:0	RW	0x01	pclk_bus_root_div Divide pclk_bus_root by (div_con + 1).

CRU_CLKSEL_CON23

Address: Operational Base(0xFF9A0000) + offset (0x035C)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15	RO	0x0	reserved
14:9	RW	0x01	stclk_m0_div Divide stclk_m0 by (div_con + 1).
8:6	RW	0x0	clk_timer0_ch5_sel clk_timer0_ch5 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_div_100m 3'b010: clk_deepslow 3'b011: clk_core_pvtpll_logic 3'b100: mclk_asrc1
5:3	RW	0x0	clk_timer0_ch4_sel clk_timer0_ch4 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_div_100m 3'b010: clk_deepslow 3'b011: clk_core_pvtpll_logic 3'b100: mclk_asrc0
2:0	RW	0x0	clk_timer0_ch3_sel clk_timer0_ch3 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_div_100m 3'b010: clk_deepslow 3'b011: clk_core_pvtpll_logic 3'b100: sai3_mclk_io_in 3'b101: sai3_sclk_io_in

CRU_CLKSEL_CON29

Address: Operational Base(0xFF9A0000) + offset (0x0374)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15	RO	0x0	reserved
14:12	RW	0x0	sclk_uart0_sel sclk_uart0 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_mux_gate 3'b010: clk_v0pll_mux_gate 3'b011: clk_frac_uart_matrix0 3'b100: clk_frac_uart_matrix1

Rockchip Confidencial

Bit	Attr	Reset Value	Description
			3'b101: clk_frac_common_matrix0 3'b110: clk_frac_common_matrix1 3'b111: clk_frac_common_matrix2
11:7	RW	0x00	sclk_uart0_div Divide sclk_uart0 by (div_con + 1).
6:5	RW	0x0	hclk_lsperi_root_sel hclk_lsperi_root clock mux. 2'b00: clk_gpll_div 2'b01: clk_v0pll_div 2'b10: clk_v1pll_div
4:0	RW	0x01	hclk_lsperi_root_div Divide hclk_lsperi_root by (div_con + 1).

CRU_CLKSEL_CON30

Address: Operational Base(0xFF9A0000) + offset (0x0378)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:13	RW	0x0	sclk_uart2_sel sclk_uart2 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_mux_gate 3'b010: clk_v0pll_mux_gate 3'b011: clk_frac_uart_matrix0 3'b100: clk_frac_uart_matrix1 3'b101: clk_frac_common_matrix0 3'b110: clk_frac_common_matrix1 3'b111: clk_frac_common_matrix2
12:8	RW	0x00	sclk_uart2_div Divide sclk_uart2 by (div_con + 1).
7:5	RW	0x0	sclk_uart1_sel sclk_uart1 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_mux_gate 3'b010: clk_v0pll_mux_gate 3'b011: clk_frac_uart_matrix0 3'b100: clk_frac_uart_matrix1 3'b101: clk_frac_common_matrix0 3'b110: clk_frac_common_matrix1 3'b111: clk_frac_common_matrix2
4:0	RW	0x00	sclk_uart1_div Divide sclk_uart1 by (div_con + 1).

Rockchip Confidencial

CRU_CLKSEL_CON31

Address: Operational Base(0xFF9A0000) + offset (0x037C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:13	RW	0x0	sclk_uart4_sel sclk_uart4 clock mux. 3'b000: xin_osc0_func 3'b001: clk_gpll_mux_gate 3'b010: clk_v0pll_mux_gate 3'b011: clk_frac_uart_matrix0 3'b100: clk_frac_uart_matrix1 3'b101: clk_frac_common_matrix0 3'b110: clk_frac_common_matrix1 3'b111: clk_frac_common_matrix2
12:8	RW	0x00	sclk_uart4_div Divide sclk_uart4 by (div_con + 1).

2.6.2 Detail Registers Description

CRU_PMU_GPLL_CON0

Address: Operational Base(0xFF9B0000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15	RW	0x0	bypass PLL Bypass. FREF bypasses PLL to FOUTPOSTDIV 1'b0: No bypass 1'b1: Bypass
14:12	RW	0x2	postdiv1 First Post Divide Value, (1-7) Should obey the rule: postdiv1 > = postdiv2
11:0	RW	0x0c8	fbdiv Feedback Divide Value, valid divider settings are: [16, 2500] in integer mode [20, 500] in fractional mode Tips: No plus one operation

CRU_PMU_GPLL_CON1

Address: Operational Base(0xFF9B0000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:14	RO	0x0	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
13	RW	0x0	pllpd PLL global power down request 1'b0: No power down 1'b1: Power down
12	RW	0x1	dsmpd PLL delta sigma modulator enable 1'b0: Modulator is enable 1'b1: Modulator is disabled
11	RO	0x0	reserved
10	RW	0x0	pll_lock PLL lock status 1'b0: Unlock 1'b1: Lock
9	RO	0x0	reserved
8:6	RW	0x1	postdiv2 Second Post Divide Value, (1-7)
5:0	RW	0x03	refdiv Reference Clock Divide Value, (1-63)

CRU_PMU_GPLL_CON2

Address: Operational Base(0xFF9B0000) + offset (0x0008)

Bit	Attr	Reset Value	Description
31:28	RO	0x0	reserved
27	RW	0x0	fout4phasepd Power down 4-phase clocks and 2X, 3X, 4X clocks 1'b0: No power down 1'b1: Power down
26	RW	0x0	foutvcopd Power down buffered VCO clock 1'b0: No power down 1'b1: Power down
25	RW	0x0	foutpostdivpd Power down all outputs except for buffered VCO clock 1'b0: No power down 1'b1: Power down
24	RW	0x0	dacpd Power down quantization noise cancellation DAC 1'b0: No power down 1'b1: Power down
23:0	RW	0x000000	fracdiv Fractional part of feedback divide (fraction = FRAC/2^24)

CRU_PMU_GPLL_CON3

Address: Operational Base(0xFF9B0000) + offset (0x000C)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:13	RO	0x0	reserved
12:8	RW	0x00	ssmod_spread Set modulation depth (spread percentage) of SSMOD 5'h0: 0% 5'h1: 0.1% 5'h2: 0.2% ... 5'h1e: 3% 5'h1f: 3.1%
7:4	RW	0x0	ssmod_divval Divider required to set the modulation frequency
3	RW	0x0	ssmod_downspread Selects center spread or downs spread 1'b0: Center spread 1'b1: Down spread
2	RW	0x1	ssmod_reset Reset modulator state 1'b0: No reset 1'b1: Reset
1	RW	0x1	ssmod_disable_sscg Bypass SSMOD by module 1'b0: No bypass 1'b1: Bypass
0	RW	0x1	ssmod_bp Bypass SSMOD by integration 1'b0: No bypass 1'b1: Bypass

CRU_PMU_GPLL_CON4

Address: Operational Base(0xFF9B0000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

2.7 SCRU PMU Register Description

2.7.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

2.7.2 Registers Summary

Name	Offset	Size	Reset Value	Description
SCRU_PMU_GATE_CON60	0x0040	W	0x00000000	Internal clock gate and division register 60

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

2.7.3 Detail Registers Description

SCRU_PMU_GATE_CON60

Address: Operational Base(0xFF9B8000) + offset (0x0040)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:1	RO	0x0000	reserved
0	RW	0x0	pclk_pmu_sgrf_en pclk_pmu_sgrf clock gating control. When high, disable clock

2.8 Application Notes

2.8.1 PLL Usage

2.8.1.1 PLL Frequency Configuration

FBDIV, POSTDIV1, BYPASS can be configured by programming CRU_xPLL_CON0.
DSMPD, REFDIV, POSTDIV2 can be configured by programming CRU_xPLL_CON1.
FRAC can be configured by programming CRU_xPLL_CON2(x= D, G).

- If DSMPD = 1 (DSM is disabled, "integer mode")

FOUTVCO = (FREF/ REFDIV)* FBDIV
FOUTPOSTDIV = FOUTVCO/ (POSTDIV1* POSTDIV2)

Rockchip Confidencial

When FREF is 24MHz, and if 800MHz FOUTPOSTDIV is needed. The configuration can be:

DSMPD = 1
REFDIV = 6
FBDIV = 200
POSTDIV1=1
POSTDIV2=1

And then

FOUTVCO = (FREF / REFDIV) * FBDIV = 24/6*200=800
FOUTPOSTDIV = FOUTVCO / (POSTDIV1*POSTDIV2)=800/1/1=800

- If DSMPD = 0 (DSM is enabled, "fractional mode")

FOUTVCO = (FREF / REFDIV) * (FBDIV + FRAC / (2^24))
FOUTPOSTDIV = FOUTVCO / (POSTDIV1*POSTDIV2)

When FREF is 24MHz, and if 491.52MHz FOUTPOSTDIV is needed. The configuration can be:

DSMPD = 0
REFDIV = 1
FBDIV = 40
FRAC = 24'hf5c28f
POSTDIV1=2
POSTDIV2=1

And then

FOUTVCO = (FREF / REFDIV) * (FBDIV + FRAC / (2^24)) = 983.04
FOUTPOSTDIV = FOUTVCO / (POSTDIV1*POSTDIV2)=983.04/(2*1)=491.52

- POSTDIV1=0, POSTDIV2=0 are unused. We should make sure that POSTDIV1>=POSTDIV2.

2.8.1.2 PLL Setting Consideration

- For lowest power operation, the minimum VCO and FREF frequencies should be used. For minimum jitter operation, the highest VCO and FREF frequencies should be used.
- The supply rejection will be worse at the low end of the VCO range so care should be taken to keep the supply clean for low power applications.
- The PD input places the PLL into the lowest power mode. In this case, all analog circuits are turned off and FREF will be "ignored". The FOUTPOSTDIV and FOUTVCO pins are forced to logic low (0V).
- The BYPASS pin controls FREF to be passed to the FOUTPOSTDIV when active high.

2.8.1.3 PLL Frequency Change And Lock Check

For normal applications, user should configure as following steps to change the PLL output frequency.

- Change PLL from normal to slow mode by programming CRU_MODE_CON00.
- Power down PLL
- Change PLL setting.
- Power up PLL after delay 1us
- Wait until PLL is lock state by checking CRU_xPLL_CON1[10] register (The max lock time is 500*REFDIV/FREF) or just delay about 500 REF_CLK cycles
- Change PLL into normal mode

For special applications, user can use on-the-fly mode. User can change FBDIV and FRAC slightly and don't need to follow above normal changing setups, PLL will simply slew to the new frequency.

2.8.2 Divider Usage

CRU supports multi-dividers for different clock requirement.

- Divider free divider
- Fractional divider
- DivfreeDT50 divider (DT50)

2.8.2.1 DivFree Divider Usage

Using this divider, freq_out =freq_src/(n+1).

2.8.2.2 Fractional Divider Usage

To get specific frequency, matrix array clocks of clk_frac_uart_matrix0/1, clk_frac_voice_matrix0/1, clk_frac_common_matrix0/1/2 can be generated by fractional

Rockchip Confidencial

divider. Generally you should ensure that denominator is 20 times larger than numerator to generate precise clock frequency. So the fractional divider applies only to generate low frequency clock.

2.8.2.3 DivfreeDT50 Divider Usage

Some modules like SDMMC, FLEXBUS, MAC, PDM and FSPI need clock of 50% duty cycle, divfreeDT50 can generate clock of 50% duty cycle even when divisor value is odd.

2.8.3 Global Software Reset

Two global software resets are designed in the chip. These two software resets are self-de-asserted by hardware. Hold time of global software reset (glb_srstn_1, glb_srstn_2, wdt_rstn, tsadc_rstn) can be programed up to 11.18s.

- CRU_GLB_SRST_FST_VALUE[15:0] = 0xfdb9 to assert the first global software reset glb_srstn_1
- CRU_GLB_SRST_SND_VALUE[15:0] = 0xeca8 to assert the second global software reset glb_srstn_2
- glb_srstn_1 resets almost all logic except some registers just supporting hardware reset
- glb_srstn_2 resets almost all logic except GPIOs, IOCs, SPINLOCK and KEYREADER.

Reset for IP in PD_PMU can be hold if its reset_hold_enable in GRF_PMU_SOC_CON3 is high even if glb_srstn_1 or glb_srstn_2 active.

2.8.4 SSCG Usage

There are some scenes where SSCG should be enabled. One scene is in communication where a fixed frequency is required. Another scene is that the system requires a clock with low long-term jitter. When SSCG is used, the PLL should be configured to fractional mode first for spread spectrum capability.

2.8.4.1 SSCG Use InternalPoint Table

User can use SSCG with internal point table as following steps:

- Setting ssmod_spread (CRU_XPLL_CON3[12:8]) and ssmod_downspread (CRU_XPLL_CON3[3])

The modulation amplitude is controlled by the value of ssmod_spread. A ssmod_spread value of 5'd0 turns off the modulation. A ssmod_spread value of 5'd31 (5'b11111) gives maximum modulation while a value of 5'd1 gives minimum modulation.

The modulation amplitude can be calculated from the value of modulation by:

Modulation Amplitude = ±5'd(ssmod_spread)*0.1%

The modulation direction is determined by the ssmod_downspread bit.

- ssmod_downspread = 1'b1, down spread mode is used. If ssmod_spread = 5'd29, the maximum PLL frequency is the nominally programmed value F_{NOM}, and the minimum value is given by F_{NOM}* (1–0.029).
- ssmod_downspread = 1'b0, center spread mode is used. If ssmod_spread = 5'd29, the maximum PLL frequency would be determined by F_{NOM}* (1+0.029) and the minimum frequency by F_{NOM} * (1–0.029).

Setting the style of modulation (center versus down) and the modulation amplitude depend on the amount of EMI reduction desired and the timing margin for circuits running on the spread clock domain. The larger the spread value, the greater the reduction in EMI amplitude. However, the larger the spread value, the more timing margin needed for correct circuit operation.

- Setting ssmod_sel_ext_wave (CRU_XPLL_CON4[0])=1'b0

When use internal point table, the frequency will change as following during 128 point:

- Change from minimum value to maximum value uniformly within 64 points
- Change from maximum value to minimum value uniformly within 64 points

Spread spectrum modulator is implemented by repeating as above.

- Setting ssmod_divval (CRU_XPLL_CON3[7:4])

The frequency of modulation FMOD= FREF / (Point number*REFDIV * ssmod_divval). The FMOD is typically set above 32KHz and below the maximum frequency for modulation fidelity, which isdetermined by the PLL bandwidth. The maximum modulation frequency is conservatively set at FREF / (200*REFDIV).

When FREF=24MHz and REFDIV= 1, the value of ssmod_divval can be 5, then the FMOD is 37.5KHz.

Rockchip Confidential

- Setting ssmod_bp (CRU_XPLL_CON3[0])=1'b0
- Setting ssmod_disable_sscg (CRU_XPLL_CON3[1])=1'b0
- Setting ssmod_reset (CRU_XPLL_CON3[2])=1'b0

2.8.4.2 SSCG Use External Point Table

In addition to the internal shape table, an external shape table can be used.
This enables customization tables in both shape and the number of sample points for theenvelope wave formup to 128 data points. The external table of 128 data points can be configured from CRU_PMU_SSGTBL0_3 ~ CRU_PMU_SSGTBL124_127.
User can use SSMOD with external point table as following steps:

- Setting ssmod_spread (CRU_XPLL_CON3[12:8]) andssmod_downspread (CRU_XPLL_CON3[3]), same with internal point table usage.
- Setting ssmod_sel_ext_wave (CRU_XPLL_CON4[0])=1'b1
- Setting ssmod_ext_maxaddr (CRU_XPLL_CON4[15:8]) and table0 ~ table127 (CRU_PMU_SSGTBL0_3 ~ CRU_PMU_SSGTBL124_127)

ssmod_ext_maxaddr is the maximum table address. For example, if the number of points describing the envelope shape is 128, the ssmod_ext_maxaddr should be configured to 127. The table address circulate over the range 0 to 127.
The table0 ~ table127 must be 8 bit numbers in the form of sign and magnitude.

  - 1.00 is represented by 8'b01111111, it is corresponded to maximum frequency.
  - -1.00 is represented in the table by 8'b11111111, it is corresponded to minimum frequency.
  - 0.5 is represented in the table by 8'b00111111.
  - -0.5 is represented in the table by 8'b10111111.

The frequency will change base table0~table127 within 128 points, and then repeat.

- Setting ssmod_divval (CRU_XPLL_CON3[7:4])

The frequency of modulation FMOD= FREF/(Point number*REFDIV*ssmod_divval). The point number equals to ssmod_ext_maxaddr+1.

- Setting ssmod_bp (CRU_XPLL_CON3[0])=1'b0
- Setting ssmod_disable_sscg (CRU_XPLL_CON3[1])=1'b0
- Setting ssmod_reset (CRU_XPLL_CON3[2])=1'b0

2.8.5 Others

Based on special requirements, the frequency of aclk_bus_root must be greater than or equal to twice the frequency of pclk_bus_root.

Chapter 3 Cortex-A7

3.1 Overview

The Cortex-A7 subsystem of the device is based on the ARMv7-A architecture. The Cortex-A7 has three Cortex-A7 central processing unit (CPU). Each processor has 16KB of Level 1 (L1) instruction cache, 16KB of L1 data cache, NEON and FPU. The Cortex-A7 also includes 128KB of Level 2 (L2) cache, Snoop Control Unit(SCU), Generic Interrupt Controller (GIC), and standard CoreSight components to support SMP debug and emulation.
The key features of the Cortex-A7 include:

- ARM Cortex-A7
  - Full implements the ARMv7-A architecture profile that includes the Advanced SIMD and VFP Extensions
  - 3 Cortex-A7 processor cores
  - 16KB L1 I-Cache and 16KB L1 D-Cache per CPU
  - In-order pipeline with direct and indirect branch prediction
  - Harvard L1 memory system with a Memory Management Unit (MMU)
  - SCU ensures memory coherency
  - Interrupt controller with 128 hardware interrupt inputs
- 128KB L2 cache
  - Fixed line length of 64 bytes
  - Physically indexed and tagged cache
  - 8-way set-associative cache structure
  - Pseudo-random cache replacement policy

Chapter 4 Cortex-M0

4.1 Overview

The Cortex-M0 processor is a very low gate count, highly energy efficient processor that is intended for micro-controller and deeply embedded applications that require an area optimized processor.

4.1.1 Cortex-M0

The following features may or may not be present in the actual product. Please contact Rockchip for the actual feature configurations and the third-party licensing requirements. The processor features and benefits are:

- A low gate count processor that features
  - The ARMv6-M Thumb instruction set
  - Thumb-2 technology
  - Load/store-multiples and multi cycle-multiplies that can be abandoned and restarted to facilitate rapid interrupt handling
  - Low power sleep-mode entry using Wait For Interrupt (WFI), Wait For Event (WFE) instructions, or the return from interrupt sleep-on-exit feature
- NVIC that features
  - 32 external interrupt inputs, each with four levels of priority
  - Dedicated Non-Maskable Interrupt (NMI) input
  - Optional Wake-up Interrupt Controller (WIC), providing ultra-low power sleep mode support
- Optional debug support
  - Two hardware breakpoints
  - One watch points
  - Support Serial Wire debug connection
  - single 32-bit AMBA-3 AHB-Lite system interface
- Integrated Interrupt Controller for APB bus, up to 128 IRQ lines with 128to4 INTMUX

4.2 Block Diagram

Cortex-M0 Integration architecture is shown below.

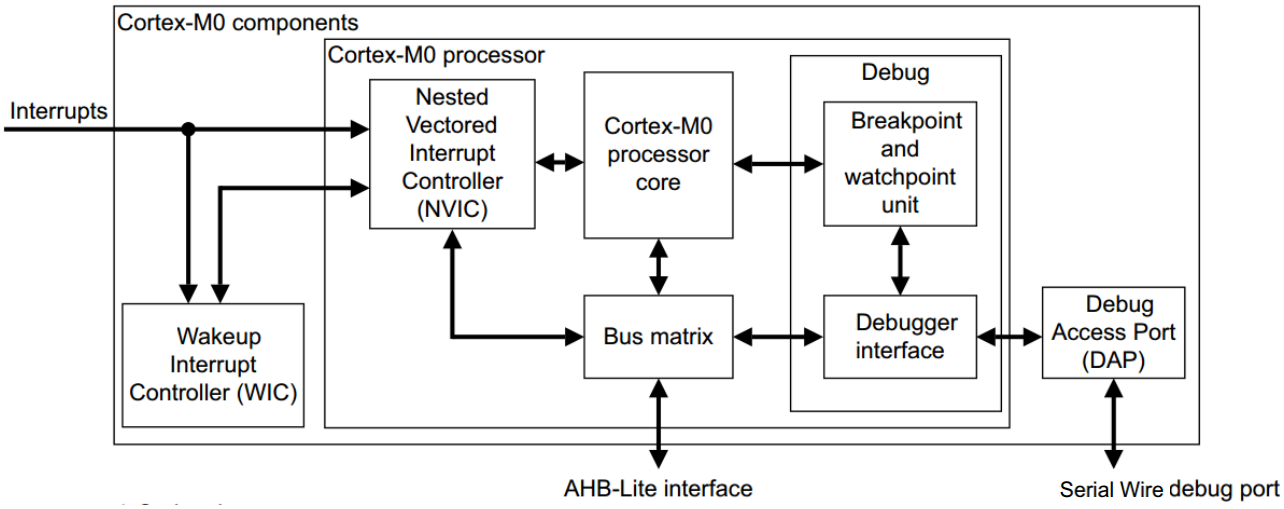

Fig. 4-1 Cortex-M0 Integration Architecture

4.3 Function Description

Please refer to the document Cortex-M0_TechnicalReferenceManualRevC_DDI0432_r0p0-02rel0.pdf and DUI0497A_cortex_m0_r0p0_generic_ug.pdf for the detail description.

4.3.1 Interrupt Multiplexer(INTMUX)

The Interrupt Multiplexer will select 4 interrupts from 125 interrupts using round robin algorithm. You need to configure corresponding enable bit for each interrupt. Also you could read the flag register to obtain the interrupt in service.

Confidencial

4.4 Register Description

Please refer to the document Cortex-M0_TechnicalReferenceManualRevC_DDI0432_r0p0-02rel0.pdf and DUI0497A_cortex_m0_r0p0_generic_ug.pdf for the detail description.

4.4.1 INTMUX Registers Summary

Operational Base

Name	Base Address
M0 INTMUX base address	0xFF2A0000

Name	Offset	Size	Reset Value	Description
INTMUX_IRQ_MASK0	0x0000	W	0x00000000	IRQ interrupt source mask0 register.
INTMUX_IRQ_MASK1	0x0004	W	0x00000000	IRQ interrupt source mask1 register.
INTMUX_IRQ_MASK2	0x0008	W	0x00000000	IRQ interrupt source mask2 register.
INTMUX_IRQ_MASK3	0x000C	W	0x00000000	IRQ interrupt source mask3 register.
INTMUX_IRQ_FLAG0	0x0080	W	0x00000000	IRQ flag0 register.
INTMUX_IRQ_FLAG1	0x0084	W	0x00000000	IRQ flag1 register.
INTMUX_IRQ_FLAG2	0x0088	W	0x00000000	IRQ flag2 register.
INTMUX_IRQ_FLAG3	0x008C	W	0x00000000	IRQ flag3 register.

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access*

4.4.2 Detail Registers Description

INTMUX_IRQ_MASK0

Address: Operational Base + offset (0x0000)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	mask0 Interrupt mask bits for the IRQ0~IRQ31 (see Table 1-5) interrupt sources. Set 1 in any bit position unmasks the corresponding interrupt. By default, all bits are masked. 1'b1: unmask interrupt 1'b0: mask interrupt

INTMUX_IRQ_MASK1

Address: Operational Base + offset (0x0004)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	Mask1 Interrupt mask bits for the IRQ32~IRQ63 (see Table 1-5) interrupt sources. Set 1 in any bit position unmasks the corresponding interrupt. By default, all bits are masked. 1'b1: unmask interrupt 1'b0: mask interrupt

INTMUX_IRQ_MASK2

Address: Operational Base + offset (0x0008)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	Mask2 Interrupt mask bits for the IRQ64~IRQ95 (see Table 1-5) interrupt sources. Set 1 in any bit position unmasks the corresponding interrupt. By default, all bits are masked. 1'b1: unmask interrupt 1'b0: mask interrupt

INTMUX_IRQ_MASK3

Address: Operational Base + offset (0x000C)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:30	RO	0x0	reserved
29:0	RO	0x00000000	Mask3 Interrupt mask bits for the IRQ96~IRQ125 (see Table 1-5) interrupt sources. Set 1 in any bit position unmasks the corresponding interrupt. By default, all bits are masked. 1'b1: unmask interrupt 1'b0: mask interrupt

INTMUX_IRQ_FLAG0

Address: Operational Base + offset (0x0080)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	int_flag0 Interrupt status after the masking stage. These are the interrupt status signals for the IRQ0~IRQ31 (see Table 1-5) interrupt sources.

INTMUX_IRQ_FLAG1

Address: Operational Base + offset (0x0084)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	int_flag1 Interrupt status after the masking stage. These are the interrupt status signals for the IRQ32~IRQ63 (see Table 1-5) interrupt sources.

INTMUX_IRQ_FLAG2

Address: Operational Base + offset (0x0088)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	int_flag2 Interrupt status after the masking stage. These are the interrupt status signals for the IRQ64~IRQ95 (see Table 1-5) interrupt sources.

INTMUX_IRQ_FLAG3

Address: Operational Base + offset (0x008C)

Bit	Attr	Reset Value	Description
31:30	RO	0x0	reserved
29:0	RO	0x00000000	int_flag3 Interrupt status after the masking stage. These are the interrupt status signals for the IRQ96~IRQ125 (see Table 1-5) interrupt sources.

4.5 Interface Description

Table 4-1 Cortex-M0 Interface Description

Module Pin	Direction	Pin Name	IOMUX Setting
m0jtag_tck_m0	I	SDMMC_D2/JTAG_TCK_M0/GPIO3_A4_d	GPIO3A_IOMUX_SEL_1[3:0] = 4'h2 GRF_SOC_CON0[4] = 1'b1
m0jtag_tms_m0	I/O	SDMMC_D3/JTAG_TMS_M0/GPIO3_A5_d	GPIO3A_IOMUX_SEL_1[7:4] = 4'h2 GRF_SOC_CON0[4] = 1'b1
m0jtag_tck_m1	I	UART0_TX/JTAG_TCK_M1/RM_IO22/GPIO0_C6_u	GPIO0C_IOMUX_SEL_1[11:8] = 4'h2 GRF_SOC_CON0[5] = 1'b1
m0jtag_tms_m1	I/O	UART0_RX/JTAG_TMS_M1/RM_IO23/GPIO0_C7_u	GPIO0C_IOMUX_SEL_1[15:12] = 4'h2 GRF_SOC_CON0[5] = 1'b1

Notes: I=input, O=output, I/O=input/output, bidirectional

4.6 Application Notes

4.6.1 Clock and Reset Generation

Please refer to "Chapter CRU" for more detailed information.

4.6.2 Miscellaneous Signals for M0

M0 System Configure Signals

Table 4-2 M0 System Configure Signals

Signal Name	Default	Description
grf_con_mcu_irqlatency[7:0]	0	Minimum number of cycles between an interrupt that becomes pended in the NVIC, and the vector fetch for that interrupt being issued
grf_con_mcu_nmi	0	Non-maskable interrupt
grf_con_mcu_dbgrestart	0	External restart request.
grf_con_mcu_edbgrq	0	External debug request.
grf_con_mcu_stcalib[25:0]	0	Systick timer counter
grf_con_mcu_rxev	0	A HIGH level on this input causes the architecture defined Event Register to be set in the Cortex-M0 processor. This causes a WFE instruction to complete. It also awakens the processor if it is sleeping as the result of encountering a WFE instruction when the Event Register is clear.
grf_con_mcu_dbgen	0	SerialWire Debug enable. 0: disable 1: enable
grf_con_mcu_sleepholdreqn	1	Request to extend the processor sleeping state regardless of wake-up events. If the processor acknowledges this request driving SLEEPHOLDACKn Low, this guarantees the processor remains idle even on receipt of a wake-up event

M0 System Status Signals

Table 4-3 M0 System Status Signals

Signal Name	Default	Description
grf_mcu_dbgrestarted	1	Handshake for DBGRESTART
grf_mcu_halted	0	Indicates that the processor is in debug state. HALTED remains asserted for as long as the processor remains in debug state.
grf_mcu_txev	0	M0 transform a event
grf_mcu_lockup	0	Indicates that m0 is locked up
grf_mcu_hclk_gate	0	Indicates that hclk can be gated.
grf_mcu_wakeup	0	Indicates M0 wakeup
grf_mcu_sleepdeep	0	Indicates the processor is idle, waiting for an interrupt on either the IRQ, NMI, or HIGH level on RXEV.
grf_mcu_sleeping	0	Active only when SLEEPING is HIGH. Indicates that the SLEEPDEEP bit in the NVIC is set to 1.
grf_mcu_sleepholdack	1	Indicates M0 sleepholdack

4.6.3 Interrupt for M0

Table 4-4 M0 Interrupt

Chapter 5 General Register Files (GRF)

5.1 Overview

The general register file will be used to do static setting by software, which is composed of many registers for system control. The GRF is located at several addresses.

5.2 Function Description

The function of general register file is：

- Common system control
- Record the system state

5.3 GRF Register Description

5.3.1 Registers Summary

Name	Offset	Size	Reset Value	Description
GRF_SOC_CON0	0x0000	W	0x00000444	System control register 0
GRF_SOC_CON1	0x0004	W	0x00000000	System control register 1
GRF_SOC_CON2	0x0008	W	0x00000000	System control register 2
GRF_SOC_CON3	0x000C	W	0x00000000	System control register 3
GRF_SOC_CON4	0x0010	W	0x00000000	System control register 4
GRF_SOC_CON5	0x0014	W	0x00000000	System control register 5

Chapter 6 Power Management Unit (PMU)

6.1 Overview

In order to meet low power requirements, a power management unit (PMU) is designed for controlling power resources in SOC. RK3506 PMU is dedicated for managing the power of the whole chip.

PMU supports the following features:

- Support multi voltage domains: VD_CORE, VD_LOGIC, VD_PMU, VD_PLL
- Support multi virtual power domains in VD_CORE: PD_CPU0, PD_CPU1, PD_CPU2
- Support power down/up all power domains by software or hardware
- Support power down/up all voltage domains by software or hardware
- Support CPU auto power down with two mode
- Support to clamp all VD_CORE output before power off VD_CORE in low power mode
- Support VD_CORE power down, send scu_pwroff output to IO
- Support to clamp all VD_PMU input before power off VD_LOGIC in low power mode
- Support VD_LOGIC power down, send pmu_sleep output to IO
- Support PMU controlled by CPU or MCU for low power management
- Support respective global interrupt disable for CPU and MCU in low power mode
- Support BIU idle operations: BIU_CPU, BIU_CPU_P, BIU_BUS, BIU_DDR, BIU_VIO, BIU_HSPERI, BIU_LSPERI
- Support to send idle request to BIU for each bus domain by software or hardware
- Support clock gate mask for each bus domain by software or hardware
- Support DDR low power management
- Support PLLs power down/up by hardware in low power mode
- Support PMU clock switch to low frequency clock in low power mode
- Support OSC enable/disable request in low power mode
- Support PMU sleep hold with configurable counter
- Support PWM auto switch to GPIO during power mode
- Support wakeup reset control for full chip in power off mode
- Support PMU debug info output to IO with UART interface mode
- Support varies configurable wakeup source for low power mode
- Support combined interrupt output for alarm and second catch interrupt

6.2 Block Diagram

The following figure is the PMU block diagram. The PMU includes the 3 following sections:

- APB Interface and Register: Provide AMBA APB interface for register read and write
- System Power State Control: Provide power management for various low power modes
- Power Gating Control: Provide power gating control for power domains

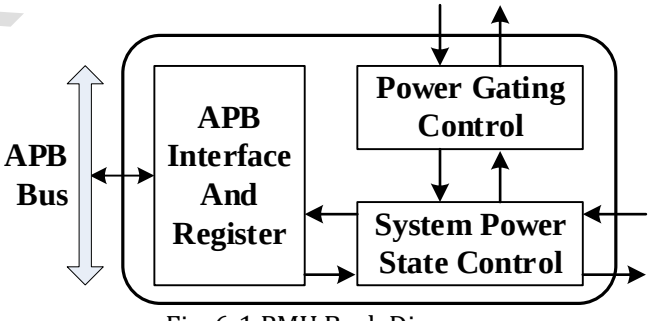

Fig. 6-1 PMU Bock Diagram

6.3 Function Description

6.3.1 Domain Partition

Rockchip Confidential

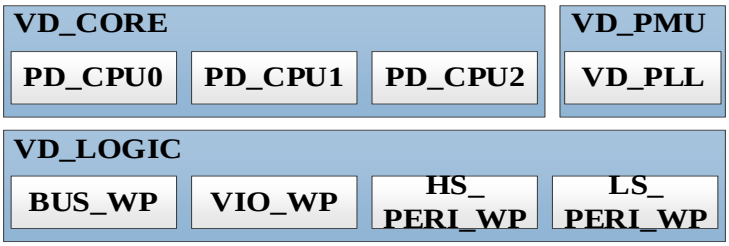

Fig. 6-2 RK3506 Voltage Domain and Power Domain Partition

The above diagram describes the power domain and voltage domain partition.

6.3.2 Operation Mode

First of all, we define two operation modes of PMU, normal mode and low power mode.
When operating at normal mode, that means software can manage power sources directly by accessing PMU registers. For example, CPU can write PMU_PWR_GATE_CON register to determine that power off/on which power domain independently.
When operating at low power mode, software manages power sources indirectly through FSM (Finite States Machine) in PMU and those settings always not take effect immediately. That means software also can configure PMU registers to power down/up some power resources, but these setting will not be executed immediately after configuration. They will be delayed to execute after FSM running in particular phase.
To enter low power mode, after setting some power configurations, the PMU_PWR_CON[0] bit must be set 1 to enable PMU FSM. Then CPU needs to execute a WFI command to perform ready signal. After PMU detects all CPUs in WFI status, the FSM will be fetched. And the specific power sources will be controlled during specific status in FSM. So the low

Rockchip Confidencial

power mode is a "delay affect" way to handle power sources inside the RK3506 chip.

6.4 Register Description

6.4.1 Registers Summary

Name	Offset	Size	Reset Value	Description

6.5 Application Notes

6.5.1 Hardware Low Power Mode

PMU can work in low power mode by hardware. After setting some power configurations and setting PMU_PWR_CON[0] to 1, you can execute the WFI command of CPU, then PMU low power FSM will start to run. In this mode, PMU will manage power resources by hardware, such as send idle request to specified power domain, auto clock switch and clock gating, shut down PLLs, and so on. All of above are configurable by setting corresponding registers.

Also, the WFI status of CPU can be bypass if PMU_SCU_PWR_CON[8] is set to 1.

6.5.2 Software Low Power Mode

PMU can work in the low power mode by software. In this application, you can use CPU or MCU to set PMU software power control registers to execute low power procedure.

6.5.3 Power Management IO Usage

There are independent power supplies for different voltage domain. You can communicate with external PMIC (Power Management Integrated Circuits) through IO interface.

Table 6-2 Power Management IO Interface

Module Pin	Direction	Pin Name	IOMUX Setting
core_pwroff/pmu_sleep	O	RM_IO	

Notes: I=input, O=output, I/O=input/output, bidirectional. For the configuration of RM_IO, please refer to chapter "Rockchip Matrix IO".

Setting PMUGRF_SOC_CON1[0] to 1 to output pmu_sleep, also, you can select the polarity by setting PMUGRF_SOC_CON1[1]. Setting PMUGRF_SOC_CON1[2] to 1 to output core_pwroff, also, you can select the polarity by setting PMUGRF_SOC_CON1[3].

Each voltage domain can generate one power off request. The voltage domain power off request can be generated as below:

(1) Enable power off control bit: Set corresponding bit to 1 in PMU_VOL_GATE_CON0.

(2) Power down internal power domain: If there is power domain included in the voltage domain, the power domain should be power down firstly. Else, skip this step.

(3) Power down voltage domain: Set corresponding bit to 1 in PMU_PWR_GATE_CON0 by hardware power gating or set corresponding bit to 1 in PMU_PWR_GATE_SFTCON0 by software power gating.

6.5.4 PMU Debug Information

The PMU internal states could be monitored through pmu_debug IO in 8-bit UART interface mode. The transmission can be enabled by setting PMU_INFO_TX_CON[8], and the transmission interval time can be set in PMU_INFO_TX_CON[7:0]. The PMU debug information is decoded as follows.

Table 6-3 PMU Debug Information Decode

Decode Value	PMU State	Description

Chapter 7 Internal SRAM

7.1 Overview

There is one Internal SRAM in RK3506, named System SRAM. System SRAM can be divided into three 16KB slices, named System SRAM0/1/2. System SRAM0/1/2 can work as AXI slave devices from System Interconnection, it also supports work as TCM from MCU AHB slave interface. System SRAM supports read and write access to provide system fast access data storage.

7.1.1 Features supported

- System SRAM
  - Support 48KB capacity
  - Include System SRAM0/1/2 internal, each of them with 16KB capacity

7.2 Block Diagram

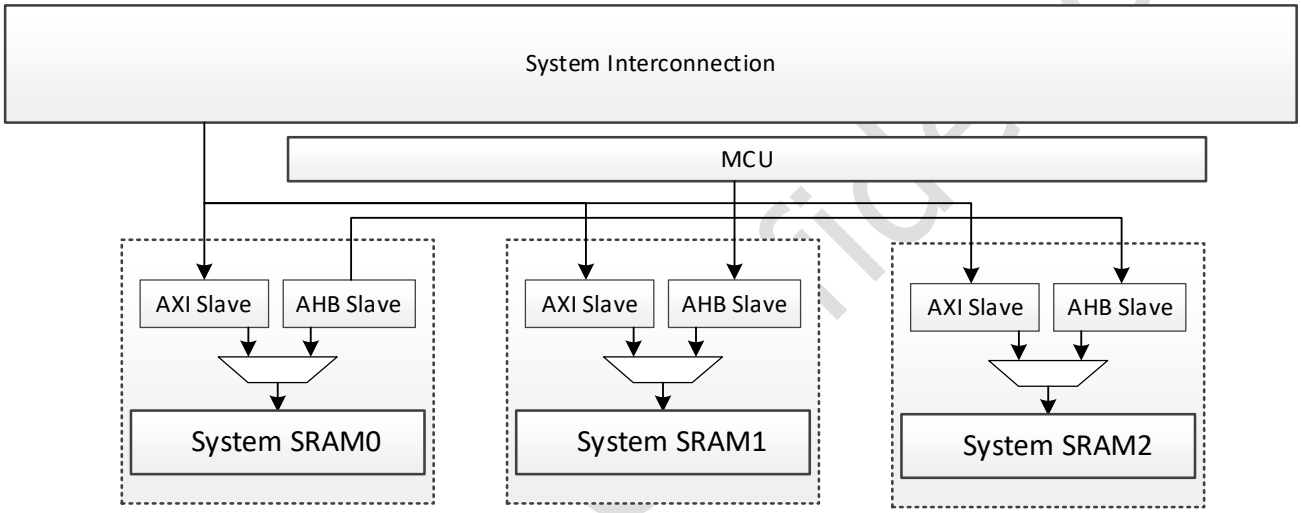

Fig.7-1 System SRAM Block Diagram

7.3 Function Description

7.3.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
System SRAM before remap address	0xfff80000
System SRAM remap address	0xfff80000
	0xffff0000

7.3.2 System SRAM Access Path

The System SRAM AXI slave device interface can be accessed by CPU, MCU, DMAC0, DMAC1, CRYPTO and SPI2, The System SRAM AHB slave device interface can be accessed by MCU.

7.3.3 System SRAM Restricted Configurations Using as TCM

System SRAM0 using as TCM is configured by mcu_tcm_sel0 in SGRF_PMU. User should configure mcu_tcm_sel0[0], mcu_tcm_sel0[1], mcu_tcm_sel0[2] to 1 in sequence when enable to used as TCM and should configure mcu_tcm_sel0[2], mcu_tcm_sel0[1], mcu_tcm_sel0[0] to 0 in sequence when disable to used as TCM.
System SRAM1 using as TCM is configured by mcu_tcm_sel1 in SGRF_PMU. User should configure mcu_tcm_sel1[0], mcu_tcm_sel1[1], mcu_tcm_sel1[2] to 1 in sequence when

Rockchip Confidential

enable to used as TCM and should configure mcu_tcm_sel1[2], mcu_tcm_sel1[1], mcu_tcm_sel1[0] to 0 in sequence when disable to used as TCM.
System SRAM2 using as TCM is configured by mcu_tcm_sel2 in SGRF_PMU. User should configure mcu_tcm_sel2[0], mcu_tcm_sel2[1], mcu_tcm_sel2[2] to 1 in sequence when enable to used as TCM and should configure mcu_tcm_sel2[2], mcu_tcm_sel2[1], mcu_tcm_sel2[0] to 0 in sequence when disable to used as TCM.

Rockchip Confidencial

Chapter 8 DMA Controller (DMAC)

8.1 Overview

RK3506 supports two Direct Memory Access (DMA) Controllers: DAMC0 and DMAC1. Both are support transfers between memory and memory, peripheral and memory. DMAC is under non-secure state after reset, and the secure state can be changed by configuring SGRF.

DMAC0 supports the following features:

- Support Trust-zone technology
- Support 12 peripheral requests
- Support up to 64bits data size
- Support 6 channels at the same time
- Support up to burst 16
- Support 4 interrupt outputs and 1 abort output
- Supports 32 MFIFO depth

Following table shows the DMAC0 request mapping scheme.

Table 8-1 DMAC0 Request Mapping Table

Request number	Source	Polarity
0	SPI0 TX/CAN0_RX/ASRC0_RX	High level
1	SPI0 RX/CAN1_RX/ASRC0_TX	High level
2	SPI1 TX/DSMC_TX/ASRC1_RX	High level
3	SPI1 RX/DSMC_RX/ASRC1_TX	High level
4	UART0 TX/CAN0_RX	High level
5	UART0 RX/CAN1_RX/PDM_RX	High level
6	UART1 TX/SPDIF_TX	High level
7	UART1 RX/SPDIF_RX	High level
8	UART2 TX/DSMC_TX/SAI0_RX	High level
9	UART2 RX/SAI0_TX	High level
10	UART3 TX/DSMC_RX/SAI1_RX	High level
11	UART3 RX/SAI1_TX	High level

DMAC1 supports the following features:

- Support Trust-zone technology
- Support 20 peripheral requests
- Support up to 64bits data size
- Support 8 channels at the same time
- Support up to burst 16
- Support 4 interrupt outputs and 1 abort output
- Support 32 MFIFO depth

Following table shows the DMAC1 request mapping scheme.

Table 8-2 DMAC1 Request Mapping Table

Request number	Source	Polarity
0	SAI0 RX	High level
1	SAI0 TX	High level
2	SAI1 RX	High level
3	SAI1 TX	High level
4	SAI2 RX	High level
5	SAI2 TX	High level
6	SAI3 TX	High level
7	SAI3 RX	High level
8	SAI4 RX	High level
9	PDM_RX	High level
10	SPDIF_TX/CAN0_RX	High level
11	SPDIF_RX/CAN1_RX	High level
12	UART4_TX	High level
13	UART4_RX	High level

Rockchip Confidential

Request number	Source	Polarity
14	UART5_TX	High level
15	UART5_RX	High level
16	ASRC0 RX	High level
17	ASRC0 TX	High level
18	ASRC1 RX	High level
19	ASRC1 TX	High level

DMAC supports incrementing-address burst and fixed-address burst. But in the case of access SPI and UART at byte or half-word size, DMAC only support fixed-address burst and the address must be aligned to word.

8.2 Block Diagram

Following figure shows the block diagram of DMAC.

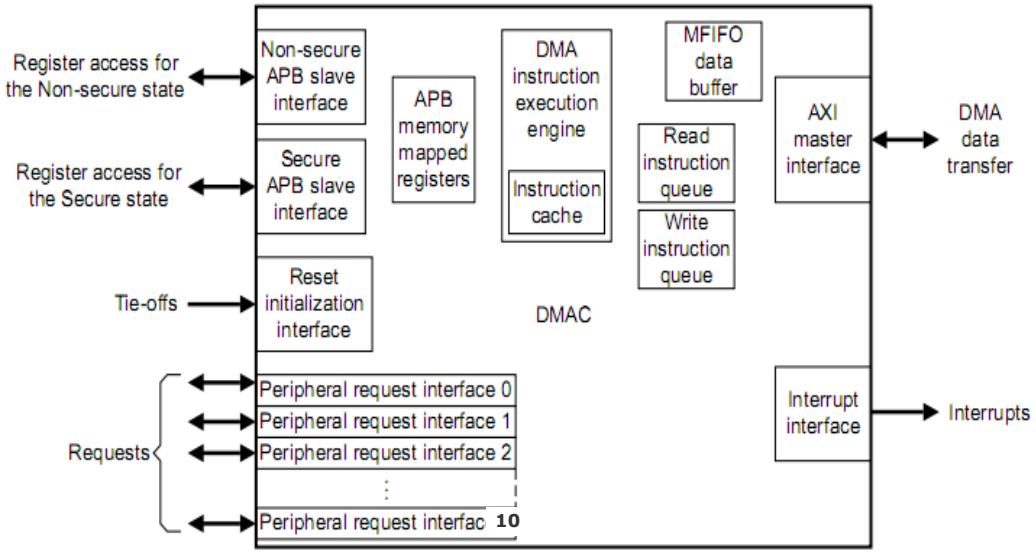

Fig. 8-1 Block diagram of DMAC

As the DMAC supports Trust-zone technology, so dual APB interfaces enable the operation of the DMAC to be partitioned into the secure state and non-secure state. You can use the APB interfaces to access status registers and also directly execute instructions in the DMAC. The default interface after reset is non-secure APB interface.

8.3 Function Description

8.3.1 Introduction

The DMAC contains an instruction processing block that enables it to process program code that controls a DMA transfer. The program code is stored in a region of system memory that the DMAC accesses using its AXI interface. The DMAC stores instructions temporarily in a cache.

DMAC0 supports 6 channels and DMAC1 supports 8 channels, each channel is capable of supporting a single concurrent thread of DMA operation. In addition, a single DMA manager thread exists, and you can use it to initialize the DMA channel threads. The DMAC executes up to one instruction for each AXI clock cycle. To ensure that it regularly executes each active thread, it alternates by processing the DMA manager thread and then a DMA channel thread. It uses a round-robin process when selecting the next active DMA channel thread to execute.

The DMAC uses variable-length instructions that consist of one to six bytes. It provides a separate Program Counter (PC) register for each DMA channel. When a thread requests an instruction from an address, the cache performs a look-up. If a cache hit occurs, then the cache immediately provides the data. Otherwise, the thread is stalled while the DMAC uses the AXI interface to perform a cache line fill. If an instruction is greater than four bytes, or spans the end of a cache line, the DMAC performs multiple cache accesses to fetch the

Rockchip Confidential

instruction.
When a cache line fill is in progress, the DMAC enables other threads to access the cache, but if another cache miss occurs, this stalls the pipeline until the first line fill is complete.
When a DMA channel thread executes a load or store instruction, the DMAC adds the instruction to the relevant read or write queue. The DMAC uses these queues as an instruction storage buffer prior to it issuing the instructions on the AXI bus. The DMAC also contains a Multi First-In-First-Out (MFIFO) data buffer that it uses to store data that it reads, or writes, during a DMA transfer.

8.3.2 Operating states

Following figure shows the operating states for the DMA manager thread and DMA channel threads.

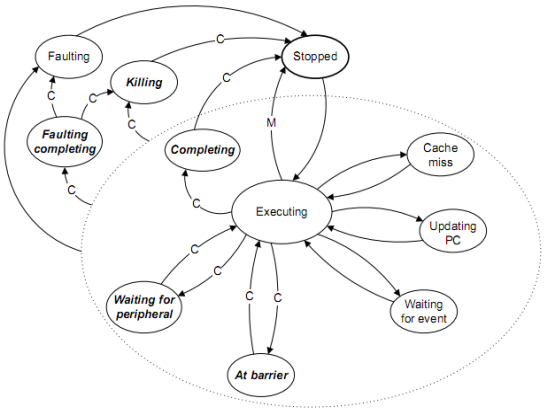

Fig. 8-2 DMAC operation states

Notes:arcs with no letter designator indicate state transitions for the DMA manager and DMA channel threads, otherwise use is restricted as follows:
C DMA channel threads only.
M DMA manager thread only.

8.4 Register Description

DMAC has two APB interfaces, secure APB and no-secure APB. You must ensure that you use the appropriate APB interface depending on the security state in which the boot_manager_ns initializes the DMAC to operate. Secure APB is only access-able from secure master. No-secure APB is access-able both from secure master and no-secure master.

Operational Base

Name	Base Address
DMAC0 secure APB base address	0xFF200000
DMAC0 no-secure APB base address	0xFF000000
DMAC1 secure APB base address	0xFF208000
DMAC1 no-secure APB base address	0xFF008000

8.4.1 Registers Summary

8.4.2 Detail Register Description

DMA_DSR

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:10	RO	0x0	Reserved
9	RO	0x0	dns 1'b0: DMA manager operates in the Secure state 1'b1: DMA manager operates in the Non-secure state
8:4	RO	0x00	wakeup_event 5'b00000: event[0] 5'b00001: event[1] 5'b00010: event[2] … 5'b11111: event[31]
3:0	RO	0x0	dma_status 4'b0000: Stopped 4'b0001: Executing 4'b0010: Cache miss 4'b0011: Updating PC 4'b0100: Waiting for event 4'b0101-4'b1110: Reserved 4'b1111: Faulting

DMA_DPC

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	pc_mgr Program counter for the DMA manager thread

DMA_INTEN

Address: **Operational Base** + offset (0x0020)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	event_irq_select Bit [N] 1'b0: If the DMAC executes DMASEV for the event-interrupt resource N then the DMAC signals event N to all of the threads. Set bit [N] to 0 if your system design does not use IRQ[N] to signal an interrupt request 1'b1: If the DMAC executes DMASEV for the event-interrupt resource N then the DMAC sets IRQ[N] HIGH. Set bit [N] to 1 if your system designer requires IRQ[N] to signal an interrupt request

DMA_EVENT_RIS

Address: **Operational Base** + offset (0x0024)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	dmasev_active Bit [N] 1'b0: Event N is inactive or IRQ[N] is LOW 1'b1: Event N is active or IRQ[N] is HIGH

DMA_INTMIS

Address: **Operational Base** + offset (0x0028)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	irq_status Bit [N] 1'b0: Interrupt N is inactive and therefore IRQ[N] is LOW 1'b1: Interrupt N is active and therefore IRQ[N] is HIGH

DMA_INTCLR

Address: **Operational Base** + offset (0x002c)

Bit	Attr	Reset Value	Description
31:0	WO	0x00000000	irq_clr Bit [N] 1'b0: The status of IRQ[N] does not change 1'b1: The DMAC sets IRQ[N] LOW if the INTEN Register programs the DMAC to signal an interrupt. Otherwise, the status of IRQ[N] does not change

DMA_FSRD

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:1	RO	0x0	Reserved
0	RO	0x0	fs_mgr 1'b0: The DMA manager thread is not in the Faulting state 1'b1: The DMA manager thread is in the Faulting state

Rockchip Confidential

DMA_FSRC

Address: **Operational Base** + offset (0x0034)

Bit	Attr	Reset Value	Description
31:8	RO	0x0	Reserved
7:0	RO	0x00	fault_status Bit [N] 1'b0: No fault is present on DMA channel N 1'b1: DMA channel N is in the Faulting or Faulting completing state

DMA_FTRD

Address: **Operational Base** + offset (0x0038)

Bit	Attr	Reset Value	Description
31	RO	0x0	Reserved
30	RO	0x0	dbg_instr Memory or from the debug interface: 1'b0: Instruction that generated an abort was read from system memory 1'b1: Instruction that generated an abort was read from the debug interface
29:17	RO	0x0	Reserved
16	RO	0x0	instr_fetch_err Performs an instruction fetch: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR, or DECERR response
15:6	RO	0x0	Reserved
5	RO	0x0	mgr_evnt_err 1'b0: The DMA manager has appropriate security to execute DMAWFE or DMASEV 1'b1: A DMA manager thread in the Non-secure state attempted to execute either: o DMAWFE to wait for a secure event o DMASEV to create a secure event or secure interrupt
4	RO	0x0	dmago_err 1'b0: The DMA manager has appropriate security to execute DMAGO 1'b1: A DMA manager thread in the Non-secure state attempted to execute DMAGO to create a DMA channel operating in the Secure state
3:2	RO	0x0	Reserved
1	RO	0x0	operand_invalid The configuration of the DMAC: 1'b0: Valid operand 1'b1: Invalid operand

Rockchip Confidencial

Bit	Attr	Reset Value	Description
0	RW	0x0	undef_instr 1'b0: Defined instruction 1'b1: Undefined instruction

DMA_FTR0

Address: **Operational Base** + offset (0x0040)

Bit	Attr	Reset Value	Description
31	RO	0x0	lockup_err 1'b0: DMA channel has adequate resources 1'b1: DMA channel has locked-up because of insufficient resources This fault is an imprecise abort.
30	RO	0x0	dbg_instr Memory or from the debug interface: 1'b0: Instruction that generated an abort was read from system memory 1'b1: Instruction that generated an abort was read from the debug interface This fault is an imprecise abort but the bit is only valid when a precise abort occurs.
29:19	RO	0x0	Reserved
18	RO	0x0	data_read_err Thread performs a data read: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR or DECERR response This fault is an imprecise abort.
17	RO	0x0	data_write_err Thread performs a data write: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR or DECERR response This fault is an imprecise abort.
16	RO	0x0	instr_fetch_err Thread performs an instruction fetch: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR or DECERR response This fault is a precise abort.
15:14	RO	0x0	Reserved
13	RO	0x0	st_data_unavailable 1'b0: MFIFO contains all the data to enable the DMAST to complete 1'b1: Previous DMALDs have not put enough data in the MFIFO to enable the DMAST to complete This fault is a precise abort.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
12	RO	0x0	mfifo_err DMALD 1'b0: MFIFO contains sufficient space 1'b1: MFIFO is too small to hold the data that DMALD requires DMAST 1'b0: MFIFO contains sufficient data 1'b1: MFIFO is too small to store the data to enable DMAST to complete This fault is an imprecise abort.
11:8	RO	0x0	Reserved
7	RO	0x0	ch_rdwr_err To perform a secure read or secure write: 1'b0: A DMA channel thread in the Non-secure state is not violating the security permissions 1'b1: A DMA channel thread in the Non-secure state attempted to perform a secure read or secure write This fault is a precise abort.
6	RO	0x0	ch_periph_err DMASTP, or DMAFLUSHP with inappropriate security permissions: 1'b0: A DMA channel thread in the Non-secure state is not violating the security permissions 1'b1: A DMA channel thread in the Non-secure state attempted to execute either: o DMAWFP to wait for a secure peripheral o DMALDP or DMASTP to notify a secure peripheral o DMAFLUSHP to flush a secure peripheral This fault is a precise abort.
5	RO	0x0	ch_event_err 1'b0: A DMA channel thread in the Non-secure state is not violating the security permissions 1'b1: A DMA channel thread in the Non-secure state attempted to execute either: o DMAWFE to wait for a secure event o DMASEV to create a secure event or secure interrupt This fault is a precise abort.
4:2	RO	0x0	Reserved
1	RO	0x0	operand_invalid Valid for the configuration of the DMAC: 1'b0: Valid operand 1'b1: Invalid operand This fault is a precise abort.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
0	RO	0x0	undef_instr 1'b0: Defined instruction 1'b1: Undefined instruction This fault is a precise abort.

DMA_FTR1

Address: **Operational Base** + offset (0x0044)

Bit	Attr	Reset Value	Description
31	RO	0x0	lockup_err 1'b0: DMA channel has adequate resources 1'b1: DMA channel has locked-up because of insufficient resources This fault is an imprecise abort.
30	RO	0x0	dbg_instr Memory or from the debug interface: 1'b0: Instruction that generated an abort was read from system memory 1'b1: Instruction that generated an abort was read from the debug interface This fault is an imprecise abort but the bit is only valid when a precise abort occurs.
29:19	RO	0x0	Reserved
18	RO	0x0	data_read_err Thread performs a data read: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR or DECERR response This fault is an imprecise abort.
17	RO	0x0	data_write_err Thread performs a data write: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR or DECERR response This fault is an imprecise abort.
16	RO	0x0	instr_fetch_err Thread performs an instruction fetch: 1'b0: OKAY response 1'b1: EXOKAY, SLVERR or DECERR response This fault is a precise abort.
15:14	RO	0x0	Reserved
13	RO	0x0	st_data_unavailable 1'b0: MFIFO contains all the data to enable the DMAST to complete 1'b1: Previous DMALDs have not put enough data in the MFIFO to enable the DMAST to complete This fault is a precise abort.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
12	RO	0x0	mfifo_err DMALD 1'b0: MFIFO contains sufficient space 1'b1: MFIFO is too small to hold the data that DMALD requires DMAST 1'b0: MFIFO contains sufficient data 1'b1: MFIFO is too small to store the data to enable DMAST to complete This fault is an imprecise abort.
11:8	RO	0x0	Reserved
7	RO	0x0	ch_rdwr_err To perform a secure read or secure write: 1'b0: A DMA channel thread in the Non-secure state is not violating the security permissions 1'b1: A DMA channel thread in the Non-secure state attempted to perform a secure read or secure write This fault is a precise abort.
6	RO	0x0	ch_periph_err DMASTP, or DMAFLUSHP with inappropriate security permissions: 1'b0: A DMA channel thread in the Non-secure state is not violating the security permissions 1'b1: A DMA channel thread in the Non-secure state attempted to execute either: o DMAWFP to wait for a secure peripheral o DMALDP or DMASTP to notify a secure peripheral o DMAFLUSHP to flush a secure peripheral This fault is a precise abort.

8.5 Timing Diagram

Following figure shows the relationship between dma_req and dma_ack.

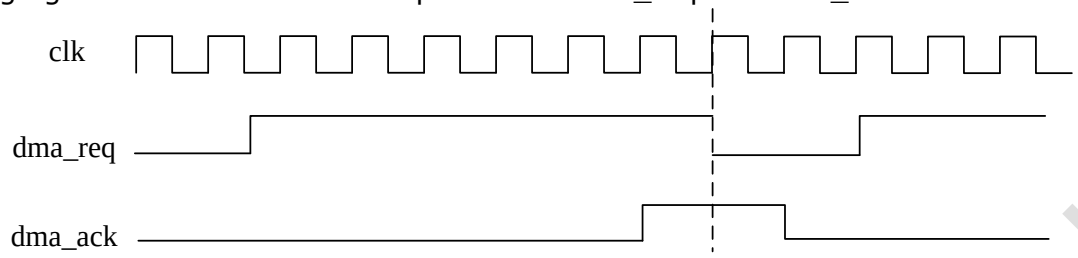

Fig. 8-3 DMAC request and acknowledge timing

8.6 Interface Description

8.6.1 DMAC boot interfaces

DMAC has the following tie-off signals. It can be configured by SGRF register. (Please refer to the chapter to find how to configure)

Table 8-3 DMAC0 boot interface

Interface	Reset value	Control source
boot_addr	0x0	Tie 0
boot_from_pc	0x0	Tie 0
boot_manager_ns	0x1	SGRF_DMAC0_CON3[0]
boot_irq_ns	0xffff	SGRF_DMAC0_CON0[11:0]
boot_periph_ns	0xffffff	SGRF_DMAC_BUS_CON1[11:0]

Table 8-4 DMAC1 boot interface

Interface	Reset value	Control source
boot_addr	0x0	Tie 0
boot_from_pc	0x0	Tie 0
boot_manager_ns	0x1	SGRF_DMAC1_CON3[0]
boot_irq_ns	0xffff	SGRF_DMAC1_CON0[15:0]
boot_periph_ns	0xffffff	{SGRF_DMAC1_CON2[3:0], SGRF_DMAC1_CON1[15:0]}

boot_addr
Configures the address location that contains the first instruction the DMAC executes, when it exits from reset.
boot_from_pc
Controls the location in which the DMAC executes its initial instruction, after it exits from reset:
1'b0: DMAC waits for an instruction from either APB interface
1'b1: DMA manager thread executes the instruction that is located at the address from boot_addr
boot_manager_ns
When the DMAC exits from reset, this signal controls the security state of the DMA manager thread:
1'b0: Assigns DMA manager to the secure state
1'b1: Assigns DMA manager to the non-secure state
boot_irq_ns
Controls the security state of an event-interrupt resource, when the DMAC exits from reset:
If boot_irq_ns[x] is low, the DMAC assigns event<x> or IRQ[x] to the secure state.

Rockchip Confidencial

If boot_irq_ns[x] is high, the DMAC assigns event<x> or IRQ[x] to the non-secure state.

boot_periph_ns

Controls the security state of a peripheral request interface, when the DMAC exits from reset:

If boot_periph_ns[x] is low, the DMAC assigns peripheral request interface x to the secure state.

If boot_periph_ns[x] is high, the DMAC assigns peripheral request interface x to the non-secure state.

8.6.2 DMAC IRQ output configure

Both DMAC0 and DMAC1 have 4 interrupt outputs, the details logic refer to the table below.

Table 8-5 DMAC interrupt interface

Interface	Signal logic	maskx source
DMAC0_IRQ	|dmac0_intr[5:0]	
DMAC0_MASK0_IRQ	|((~mask0[5:0])&dmac0_intr[5:0])	GRF_SOC_CON38[5:0]
DMAC0_MASK1_IRQ	|((~mask1[5:0])&dmac0_intr[5:0])	GRF_SOC_CON38[13:8]
DMAC0_MASK2_IRQ	|((~mask2[5:0])&dmac0_intr[5:0])	GRF_SOC_CON39[5:0]
DMAC1_IRQ	|dmac1_intr[7:0]	
DMAC1_MASK0_IRQ	|((~mask0[7:0])&dmac1_intr[7:0])	GRF_SOC_CON39[15:8]
DMAC1_MASK1_IRQ	|((~mask1[7:0])&dmac1_intr[7:0])	GRF_SOC_CON40[7:0]
DMAC1_MASK2_IRQ	|((~mask2[7:0])&dmac1_intr[7:0])	GRF_SOC_CON40[15:8]

8.6.3 DMAC peripheral request

Some of the DMAC0/1 peripheral request interfaces are configure-able for selecting different source.

Table 8-6 DMAC peripheral request

Interface	Signal logic	Control source
DMAC0_CH0_REQ	SPI0 TX/CAN0_RX/ASRC0_RX	GRF_SOC_CON42[1:0]
DMAC0_CH1_REQ	SPI0 RX/CAN1_RX/ASRC0_TX	GRF_SOC_CON42[3:2]
DMAC0_CH2_REQ	SPI1 TX/DSMC_TX/ASRC1_RX	GRF_SOC_CON42[5:4]
DMAC0_CH3_REQ	SPI1 RX/DSMC_RX/ASRC1_TX	GRF_SOC_CON42[7:6]
DMAC0_CH4_REQ	UART0 TX/CAN0_RX	GRF_SOC_CON42[9:8]
DMAC0_CH5_REQ	UART0 RX/CAN1_RX/PDM_RX	GRF_SOC_CON42[11:10]
DMAC0_CH6_REQ	UART1 TX/SPDIF_TX	GRF_SOC_CON42[13:12]
DMAC0_CH7_REQ	UART1 RX/SPDIF_RX	GRF_SOC_CON42[15:14]
DMAC0_CH8_REQ	UART2 TX/DSMC_TX/SAI0_RX	GRF_SOC_CON43[1:0]
DMAC0_CH9_REQ	UART2 RX/SAI0_TX	GRF_SOC_CON43[3:2]
DMAC0_CH10_REQ	UART3 TX/DSMC_RX/SAI1_RX	GRF_SOC_CON43[5:4]
DMAC0_CH11_REQ	UART3 RX/SAI1_TX	GRF_SOC_CON43[7:6]
DMAC1_CH10_REQ	SPDIF_TX/CAN0_RX	GRF_SOC_CON43[9:8]
DMAC1_CH11_REQ	SPDIF_RX/CAN1_RX	GRF_SOC_CON43[11:10]

8.7 Application Notes

8.7.1 Using the APB slave interfaces

You must ensure that you use the appropriate APB interface, depending on the security state in which the boot_manager_ns initializes the DMAC to operate. For example, if the DMAC is in the secure state, you must issue the instruction using the secure APB interface, otherwise the DMAC ignores the instruction. You can use the secure APB interface, or the non-secure APB interface, to start or restart a DMA channel when the DMAC is in the non-secure state.

The necessary steps to start a DMA channel thread using the debug instruction registers as following:

Rockchip Confidential

1. Create a program for the DMA channel.
2. Store the program in a region of system memory.
3. Poll the DBGSTATUS register to ensure that debug is idle, that is, the dbgstatus bit is 0.
4. Write to the DBGINST0 register and enter the:
- Instruction byte 0 encoding for DMAGO.
- Instruction byte 1 encoding for DMAGO.
- Debug thread bit to 0. This selects the DMA manager thread.

5. Write to the DBGINST1 register with the DMAGO instruction byte [5:2] data, see Debug Instruction-1 register description. You must set these four bytes to the address of the first instruction in the program, which was written to system memory in step 2.
6. Writing zero to the DBGCMD Register. The DMAC starts the DMA channel thread and sets the dbgstatus bit to 1.

8.7.2 Security usage

- **DMA manager thread is in the secure state**

If the DNS bit is 0, the DMA manager thread operates in the secure state and it only performs secure instruction fetches. When a DMA manager thread in the secure state processes:

DMAGO

It uses the status of the ns bit, to set the security state of the DMA channel thread by writing to the CNS bit for that channel.

DMAWFE

It halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding INS bit.

DMASEV

It sets the corresponding bit in the INT_EVENT_RIS Register, irrespective of the security state of the corresponding INS bit.

DMA manager thread is in the Non-secure state

If the DNS bit is 1, the DMA manager thread operates in the non-secure state, and it only performs non-secure instruction fetches. When a DMA manager thread in the non-secure state processes:

DMAGO

The DMAC uses the status of the ns bit, to control if it starts a DMA channel thread.
If ns = 0, the DMAC does not start a DMA channel thread and instead it:
1. Executes a NOP.
2. Sets the FSRD Register, see Fault Status DMA Manager.
3. Sets the dmago_err bit in the FTRD Register, see Fault Type DMA Manager Register.
4. Moves the DMA manager to the Faulting state.

If ns = 1, the DMAC starts a DMA channel thread in the non-secure state and programs the CNS bit to be non-secure.

DMAWFE

The DMAC uses the status of the corresponding INS bit, in the CR3 Register, to control if it waits for the event.
If INS = 0, the event is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the FSRD Register, see Fault Status DMA Manager Register.
3. Sets the mgr_evnt_err bit in the FTRD Register, see Fault Type DMA Manager Register.
4. Moves the DMA manager to the Faulting state.

If INS = 1, the event is in the Non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

DMASEV

The DMAC uses the status of the corresponding INS bit, in the CR3 Register, to control if it creates the event-interrupt.
If INS = 0, the event-interrupt resource is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the FSRD Register, see Fault Status DMA Manager Register.
3. Sets the mgr_evnt_err bit in the FTRD Register, see Fault Type DMA Manager Register.

Rockchip Confidential

4. Moves the DMA manager to the Faulting state.
If INS = 1, the event-interrupt resource is in the Non-secure state. The DMAC creates the event-interrupt.

DMA channel thread is in the secure state

When the CNS bit is 0, the DMA channel thread is programmed to operate in the secure state and it only performs secure instruction fetches.
When a DMA channel thread in the secure state processes the following instructions:

DMAWFE

The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding INS bit, in the CR3 Register.

DMASEV

The DMAC creates the event-interrupt, irrespective of the security state of the corresponding INS bit, in the CR3 Register.

DMAWFP

The DMAC halts execution of the thread until the peripheral signals a DMA request. When this occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding PNS bit, in the CR4 Register.

DMALDP, DMASTP

The DMAC sends a message to the peripheral to communicate that data transfer is complete, irrespective of the security state of the corresponding PNS bit, in the CR4 Register.

DMAFLUSHP

The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status, irrespective of the security state of the corresponding PNS bit, in the CR4 Register.
When a DMA channel thread is in the secure state, it enables the DMAC to perform secure and non-secure AXI accesses.

- **DMA channel thread is in the Non-secure state**

When the CNS bit is 1, the DMA channel thread is programmed to operate in the non-secure state and it only performs non-secure instruction fetches.
When a DMA channel thread in the Non-secure state processes the following instructions:

DMAWFE

The DMAC uses the status of the corresponding INS bit, in the CR3 Register, to control if it waits for the event.
If INS = 0, the event is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_evnt_err bit in the FTRn Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
If INS = 1, the event is in the non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

DMASEV

The DMAC uses the status of the corresponding INS bit, in the CR3 Register, to control if it creates the event.
If INS = 0, the event-interrupt resource is in the Secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_evnt_err bit in the FTRn Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
If INS = 1, the event-interrupt resource is in the Non-secure state. The DMAC creates the event-interrupt.

DMAWFP

The DMAC uses the status of the corresponding PNS bit, in the CR4 Register, to control if it

Rockchip Confidential

waits for the peripheral to signal a request.
If PNS = 0, the peripheral is in the Secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_periph_err bit in the FTRn Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
If PNS = 1, the peripheral is in the Non-secure state. The DMAC halts execution of the thread and waits for the peripheral to signal a request.

DMALDP, DMASTP

The DMAC uses the status of the corresponding PNS bit, in the CR4 Register, to control if it sends an acknowledgement to the peripheral.
If PNS = 0, the peripheral is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_periph_err bit in the FTRn Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
If PNS = 1, the peripheral is in the Non-secure state. The DMAC sends a message to the peripheral to communicate when the data transfer is complete.

DMAFLUSHP

The DMAC uses the status of the corresponding PNS bit, in the CR4 Register, to control if it sends a flush request to the peripheral.
If PNS = 0, the peripheral is in the secure state. The DMAC:
1. Executes a NOP.
2. Sets the appropriate bit in the FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_periph_err bit in the FTRn Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel to the Faulting completing state.
If PNS = 1, the peripheral is in the Non-secure state. The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status.
When a DMA channel thread is in the Non-secure state, and a DMAMOV CCR instruction attempts to program the channel to perform a secure AXI transaction, the DMAC:
1. Executes a DMANOP.
2. Sets the appropriate bit in the FSRC Register that corresponds to the DMA channel number. See Fault Status DMA Channel Register.
3. Sets the ch_rdwr_err bit in the FTRn Register, see Fault Type DMA Channel Registers.
4. Moves the DMA channel thread to the Faulting completing state.

8.7.3 Programming restrictions

Fixed unaligned bursts

The DMAC does not support fixed unaligned bursts. If you program the following conditions, the DMAC treats this as a programming error:
Unaligned read
- src_inc field is 0 in the CCRn Register
- the SARn Register contains an address that is not aligned to the size of data that the src_burst_size field contain

Unaligned write
- dst_inc field is 0 in the CCRn Register
- the DARn Register contains an address that is not aligned to the size of data that the dst_burst_size field contains

Endian swap size restrictions

If you program the endian_swap_size field in the CCRn Register, to enable a DMA channel to perform an endian swap then you must set the corresponding SARn Register and the corresponding DARn Register to contain an address that is aligned to the value that the endian_swap_size field contains.

Updating DMA channel control registers during a DMA cycle restriction

Prior to the DMAC executing a sequence of DMALD and DMAST instructions, the values you

Rockchip Confidential

program in to the CCRn Register, SARn Register, and DARn Register control the data byte lane manipulation that the DMAC performs when it transfers the data from the source address to the destination address. You'd better not update these registers during a DMA cycle.

Resource sharing between DMA channels

DMA channel programs share the MFIFO data storage resource. You must not start a set of concurrently running DMA channel programs with a resource requirement that exceeds the configured size of the MFIFO. If you exceed this limit then the DMAC might lock up and generate a Watchdog abort.

8.7.4 Unaligned transfers may be corrupted

For a configuration with more than one channel, if any of channels 1 to 7 is performing transfers between certain types of misaligned source and destination addresses, then the output data may be corrupted by the action of channel 0.

Data corruption might occur if all of the following are true:

1. Two beats of AXI read data are received for one of channels 1 to 7.
2. Source and destination address alignments mean that each read data beat is splited across two lines in the data buffer (see Splitting data, below).
3. There is one idle cycle between the two read data beats.
4. Channel 0 performs an operation that updates channel control information during this idle cycle (see Updates to channel control information, below).

Splitting data

Depending upon the programmed values for the DMA transfer, one beat of read data from the AXI interface need to be splited across two lines in the internal data buffer. This occurs when the read data beat contains data bytes which will be written to addresses that wrap around at the AXI interface data width, so that these bytes could not be transferred by a single AXI write data beat of the full interface width.

Most applications of DMA-330 do not split data in this way, so are NOT vulnerable to data corruption from this defect.

The following cases are not vulnerable to data corruption because they do not split data:

- Byte lane offset between source and destination addresses is 0 when source and destination addresses have the same byte lane alignment, the offset is 0 and a wrap operation that splits data cannot occur.
- Byte lane offset between source and destination addresses is a multiple of source size.

Table 8-7 Source size in CCRn

Source size in CCRn	Allowed offset between SARn and DARn
SS8	Any offset allowed.
SS16	0,2,4,6,8,10,12,14
SS32	0,4,8,12
SS64	0,8

8.7.5 Interrupt shares between channel

As the DMAC does not record which channel (or list of channels) have asserted an interrupt. So it will depend on your program and whether any of the visible information for that program can be used to determine progress, and help identify the interrupt source.

There are 4 likely information sources that can be used to determine the progress made by a program:

- Program counter (PC)
- Source address
- Destination address
- Loop counters (LC)

For example, a program might emit an interrupt each time that it iterates around a loop. In this case, the interrupt service routine (ISR) would need to store the loop value of each channel when it is called, and then compare against the new value when it is next called. A change in value would indicate that the program has progressed.

The ISR must be carefully written to ensure that no interrupts are lost. The sequence of operations is as follows:

1. Disable interrupts

Rockchip Confidential

2. Immediately clear the interrupt in DMA-330
3. Check the relevant registers for both channels to determine which must be serviced
4. Take appropriate action for the channels
5. Re-enable interrupts and exit ISR

8.7.6 Instruction sets

Table 8-8 DMAC Instruction sets

Mnemonic	Instruction	Thread usage
DMAADDH	Add Halfword	C
DMAEND	End	M/C
DMAFLUSHP	Flush and Notify Peripheral	C
DMAGO	Go	M
DMAKILL	Kill	C
DMALD	Load	C
DMALDP	Load Peripheral	C
DMALP	Loop	C
DMALPEND	Loop End	C
DMALPFE	Loop Forever	C
DMAMOV	Move	C
DMANOP	No Operation	M/C
DMARMB	Read Memory Barrier	C
DMASEV	Send Event	M/C
DMAST	Store	C
DMASTP	Store and Notify Peripheral	C
DMASTZ	Store Zero	C
DMAWFE	Wait For Event M	M/C
DMAWFP	Wait For Peripheral	C
DMAWMB	Write Memory Barrier	C
DMAADNH	Add Negative Halfword	C

Notes: Thread usage: C=DMA channel, M=DMA manager

8.7.7 Assembler directives

In this document, only DMMADNH instruction is took as an example to show the way the instruction assembled. For the other instructions, please refer to pl330_trm.pdf.

DMAADNH

Add Negative Halfword adds an immediate negative 16-bit value to the SARn Register or DARn Register, for the DMA channel thread. This enables the DMAC to support 2D DMA operations, or reading or writing an area of memory in a different order to naturally incrementing addresses. See Source Address Registers and Destination Address Registers. The immediate unsigned 16-bit value is one-extended to 32 bits, to create a value that is the two's complement representation of a negative number between -65536 and -1, before the DMAC adds it to the address using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from 0xFFFFFFFF to 0x00000000. The net effect is to subtract between 65536 and 1 from the current value in the Source or Destination Address Register.
Following table shows the instruction encoding.

Table 8-9 DMAC instruction encoding

Imm[15:8]	Imm[7:0]	0	1	0	1	1	1	ra	0

Assembler syntax

DMAADNH <address_register>, <16-bit immediate>
where:
<address_register>
Selects the address register to use. It must be either:
SAR
SARn Register and sets ra to 0.
DAR
DARn Register and sets ra to 1.

Rockchip Confidential

<16-bit immediate>

The immediate value to be added to the <address_register>.

You should specify the 16-bit immediate as the number that is to be represented in the instruction encoding. For example, DMAADNH DAR, 0xFFF0 causes the value 0xFFFFFFF0 to be added to the current value of the Destination Address Register, effectively subtracting 16 from the DAR.

You can only use this instruction in a DMA channel thread.

Rockchip Confidencial

Chapter 9 DMA2DDR

9.1 Overview

As an external memory, DDR plays an important role on SOC system. Testing DDR device, determine the DDR grain yield, to eliminate errors in data transmission is very important. Through this module mainly realize the DDR memory test, it still supports memory copy and eye diagram scanning function.

9.1.1 Features

The DMA2DDR supports the following features:

- Support one DMA channel
- Embedded a 128 bitx16 data FIFO storage space for the memory copy of the data
- Support the Word, 2 Word, 4 Word data transmitted bits wide
- Support SINGLE, INCR4, INCR8, INCR16 four bus data transmission mode
- Support data transfer complete interrupt and error interrupt
- Support test data value configuration of X, the length of X is 16 word
- Support comparison data configuration, and comparison data location configurable
- Support three kinds of method of error data processing
  - Software trigger to complete data transmission
  - Direct terminate data transmission
  - Ignore error to complete data transmission
- Support test address increasing/decreasing configurations, require transport address burst length alignment
- Support seven test pattern configuration: WW mode, W2W mode, RR mode, RC mode, RC2RC mode, RCW mode and RW mode
- Support reporting after the interruption of fault data error address, error data and error byte/word counter

9.2 Architecture

This section descripts the functions and behavior under various conditions.

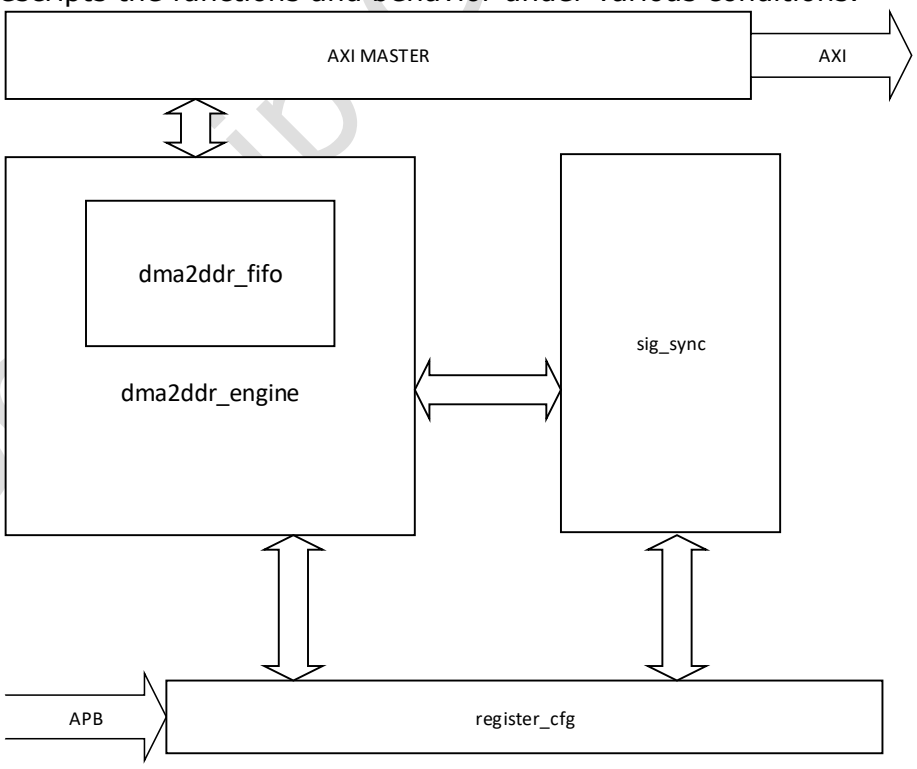

Fig. 9-1 DMA2DDR architecture

9.2.1 Block Diagram

The DMA2DDR comprises with:

- DMA2DDR register configuration block
- DMA2DDR engine block

Rockchip Confidencial

- DMA2DDR FIFO block
- DMA2DDR sig_sync block
- DMA2DDR axi_master block

9.2.2 Block Descriptions

DMA2DDR register configuration block

DMA2DDR register configuration block is used to configure the parameters of dma2ddr. This module includes all the registers which are necessary for dma2ddr working.

DMA2DDR engine block

DMA2DDR engine block is the main block of DMA2DDR module. According to the configured message, this module makes the corresponding data processing which test needed, it has write, read and compare functions of data process.

DMA2DDR FIFO block

The dma2ddr FIFO is used to store read data in RW mode, RC mode, RCW mode and RC2RC mode.

DMA2DDR sig_sync block

The sig_sync block is used to handle the signals from different clock domains.

DMA2DDR axi_master block

The axi_master block is used to implement the functions of the AXI master and communicate with engine block.

9.3 Register description

9.3.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
DMA2DDR secure base address	0x403A0000
DMA2DDR non-secure base address	0x503A0000

9.3.2 Registers Summary

Name	Offset	Size	Reset Value	Description
DMA2DDR_TMODE	0x0000	W	0x00000000	Test Mode Register
DMA2DDR_TIADDR00	0x0004	W	0x00000000	Address Register 00
DMA2DDR_TIADDR01	0x0008	W	0x00000000	Address Register 01

DMA2DDR_TIADDR00

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	iaddr00 Initial address0[31:0] for DMA2DDR test, this address is used for all the test modes.

DMA2DDR_TIADDR01

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved
2:0	RW	0x0	iaddr01 Initial address0[34:32] for DMA2DDR test, this address is used for all the test modes.

DMA2DDR_TLENGTH0

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	tlengh0 The total test length for address0. The unit is word.

DMA2DDR_TIADDR10

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	iaddr10 Initial address1[31:0] for DMA2DDR test, this address is just used for W2W mode, RC2RC mode and RCW mode.

DMA2DDR_TIADDR11

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved
2:0	RW	0x0	iaddr11 Initial address1[34:32] for DMA2DDR test, this address is just used for W2W mode, RC2RC mode and RCW mode.

Rockchip Confidencial

DMA2DDR_TLENGTH1

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	tlength1 The total test length for address1. The unit is word.

DMA2DDR_WADDR0

Address: **Operational Base** + offset (0x0024)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	waddr0 Write address[31:0] for DMA2DDR test, this address is just used for RW mode.

DMA2DDR_WADDR1

Address: **Operational Base** + offset (0x0028)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved
2:0	RW	0x0	waddr1 Write address[34:32] for DMA2DDR test, this address is just used for RW mode.

DMA2DDR_TCTL

Address: **Operational Base** + offset (0x002C)

Bit	Attr	Reset Value	Description
31	RO	0x0	reserved
30:7	RW	0x000000	slen The length of DMA2DDR single time. The unit is word. This register should be configured in RC2RC/W2W/RCW mode. When slen=0, it means the length equals burst length. Except for 0, the minimum value should be 2*BL*SIZE(BL is burst length which is from tburst, and SIZE is bus size which is from tsize).
6:5	RW	0x0	edctrl Error data deal method. 2'b00: Stop the transmission 2'b01: Wait the software trigger to continue the transmission 2'b10: Ignore error data until transmission done This register should be configured in RC/RC2RC/RCW mode, indicate the deal method when error data detected.
4	RW	0x0	torder The order of address arrangement. 1'b0: Ascending order 1'b1: Descending order

Rockchip Confidencial

Bit	Attr	Reset Value	Description
3:2	RW	0x0	tburst Burst length of DMA2DDR in transfer. 2'b00: Single transfer 2'b01: Incremental 4 transfers 2'b10: Incremental 8 transfers 2'b11: Incremental 16 transfers
1:0	RW	0x0	tsize Byte size of DMA2DDR in transfer. 2'b00: 4(1Word) 2'b01: 8(2Word) 2'b10: 16(4Word) 2'b11: Reserved

DMA2DDR_EDFLAG

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RO	0x0000	eflag Indicate error data location in the burst. 16'h1: Error in the first beat in this burst 16'h2: Error in the second beat in this burst 16'h4: Error in the third beat in this burst 16'h8: Error in the fourth beat in this burst 16'h10: Error in the fifth beat in this burst 16'h20: Error in the sixth beat in this burst 16'h40: Error in the seventh beat in this burst 16'h80: Error in the eighth beat in this burst 16'h100: Error in the ninth beat in this burst 16'h200: Error in the tenth beat in this burst 16'h400: Error in the eleventh beat in this burst 16'h800: Error in the twelfth beat in this burst 16'h1000: Error in the thirteenth beat in this burst 16'h2000: Error in the fourteenth beat in this burst 16'h4000: Error in the fifteenth beat in this burst 16'h8000: Error in the sixteenth beat in this burst

DMA2DDR_EDLOC

Address: **Operational Base** + offset (0x0034)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	edloc Configured beat location which the data you needed in burst. 16'h1: Data location in the first beat in this burst 16'h2: Data location in the second beat in this burst 16'h4: Data location in the third beat in this burst 16'h8: Data location in the fourth beat in this burst 16'h10: Data location in the fifth beat in this burst 16'h20: Data location in the sixth beat in this burst 16'h40: Data location in the seventh beat in this burst 16'h80: Data location in the eighth beat in this burst 16'h100: Data location in the ninth beat in this burst 16'h200: Data location in the tenth beat in this burst 16'h400: Data location in the eleventh beat in this burst 16'h800: Data location in the twelfth beat in this burst 16'h1000: Data location in the thirteenth beat in this burst 16'h2000: Data location in the fourteenth beat in this burst 16'h4000: Data location in the fifteenth beat in this burst 16'h8000: Data location in the sixteenth beat in this burst

DMA2DDR_EADDR0

Address: **Operational Base** + offset (0x0038)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	eaddr0 Current address[31:0] which data error detected.

DMA2DDR_EADDR1

Address: **Operational Base** + offset (0x003C)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved
2:0	RO	0x0	eaddr1 Current address[34:32] which data error detected.

DMA2DDR_EDATA0

Address: **Operational Base** + offset (0x0040)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	edata0 Detected error data[31:0] situated in which DMA2DDR_EDLOC configured.

DMA2DDR_EDATA1

Address: **Operational Base** + offset (0x0044)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	edata1 Detected error data[63:32] situated in which DMA2DDR_EDLOC configured.

Rockchip Confidential

DMA2DDR_TRCDATA33M

Address: **Operational Base** + offset (0x0134)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	trcdata33m Background data3 read compare location enable bits [127:96] for RC operation in RC2RC/RC/RCW modes.

9.4 Application Notes

Register configuration should follow:
(1) DMA2DDR_TEN should be configured in the end.
(2) When you use different test modes, the need for a particular configuration register is important, especially DMA2DDR_TCTL register. Inappropriate configuration will lead to the transmission error, you can reference DMA2DDR instruction when using it in different test mode.

Rockchip Confidential

Chapter 10 TIMER

10.1 Overview

TIMER is a programmable timer peripheral. It is usually used for generating a timing interrupt. There are two types of TIMER which are different in channel number. Both of them can be configured as a count-up or count-down timer.

TIMER supports the following features:

- Support two timer mode: free-running and user-defined
- Support two count mode: count-up and count-down
- Support configuration of loading count value
- Support mask interrupt

10.2 Block Diagram

Fig. 10-1 shows the block diagram of TIMER:

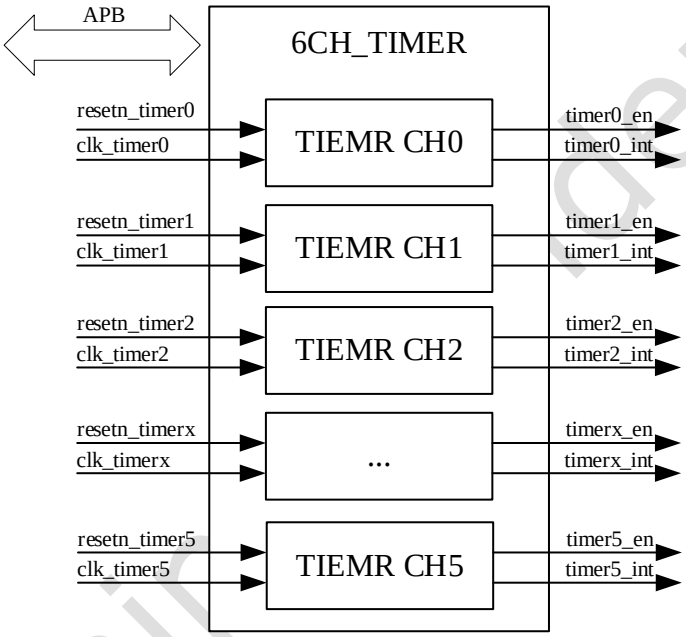

Fig. 10-1 TIMER Block Diagram

10.3 Function Description

10.3.1 TIMER Clock

The frequency of counting clock is switched between 100MHz and 24MHz.

10.3.2 Timer Mode

- **User-defined Count Mode**

TIMER loads TIMER_TIMERn_LOAD_COUNT1 and TIMER_TIMERn_LOAD_COUNT0 registers (for count-down TIMER) or zero (for count-up TIMER) as initial value. When the TIMER counts down to 0 (for count-down TIMER) or counts up to the value in TIMER_TIMERn_LOAD_COUNT1 and TIMER_TIMERn_LOAD_COUNT0 (for count-up TIMER), it will not automatically reload the count value register. User need to disable timer firstly and follow the programming sequence to make timer work again.

- **Free-running Count Mode**

TIMER loads the TIMER_TIMERn_LOAD_COUNT1 and TIMER_ TIMERn_LOAD_COUNT0 (for count-down TIMER) or zero (for count-up TIMER) register as initial value. TIMER will automatically reload the count value register, when timer counts down to 0 (for count-down TIMER) or counts up to the value in TIMER_TIMERn_LOAD_COUNT1 and

Rockchip Confidential

TIMER_TIMERn_LOAD_COUNT0 (for count-up TIMER).

10.4 Register Description

10.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
TIMER0_CH0	0xff250000
TIMER0_CH1	0xff251000
TIMER0_CH2	0xff252000
TIMER0_CH3	0xff253000
TIMER0_CH4	0xff254000
TIMER0_CH5	0xff255000
TIMER1_CH0	0xff258000
TIMER1_CH1	0xff259000
TIMER1_CH2	0xff25a000
TIMER1_CH3	0xff25b000
TIMER1_CH4	0xff25c000
TIMER1_CH5	0xff25d000

10.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
TIMER_6CH_TIMERn_LOAD_COUNT0	0x0000	W	0x00000000	Low 32 bits value to be loaded into Timer0
TIMER_6CH_TIMERn_LOAD_COUNT1	0x0004	W	0x00000000	High 32 bits value to be loaded into Timer0.
TIMER_6CH_TIMERn_CURR_VALUE0	0x0008	W	0x00000000	Low 32 bits of current value of Timer0.
TIMER_6CH_TIMERn_CURR_VALUE1	0x000C	W	0x00000000	High 32 bits of current value of Timer0.
TIMER_6CH_TIMERn_CONTROL	0x0010	W	0x00000000	Timer Control Register
TIMER_6CH_TIMERn_INTSTATUS	0x0018	W	0x00000000	Timer Interrupt Status Register
TIMER_6CH_TIMERn_REVISION	0x001C	W	0x2AF60000	Timer Version Register

TIMER1	clk_timer0	xin_osc0_func/clk_gpll_div_100m/clk_deepslow/clk_core_pvtpll_logic/sai0_mclk_io_in/sai0_sclk_io_in	100M/24M/32K
	clk_timer1	xin_osc0_func/clk_gpll_div_100m/clk_deepslow/clk_core_pvtpll_logic/sai1_mclk_io_in/sai1_sclk_io_in	100M/24M/32K
	clk_timer2	xin_osc0_func/clk_gpll_div_100m/clk_deepslow/clk_core_pvtpll_logic/sai2_mclk_io_in/sai2_sclk_io_in	100M/24M/32K
	clk_timer3	xin_osc0_func/clk_gpll_div_100m/clk_deepslow/clk_core_pvtpll_logic/sai3_mclk_io_in/sai3_sclk_io_in	100M/24M/32K
	clk_timer4	xin_osc0_func/clk_gpll_div_100m/clk_deepslow/clk_core_pvtpll_logic/mclk_asrc0	100M/24M/32K
	clk_timer5	xin_osc0_func/clk_gpll_div_100m/clk_deepslow/clk_core_pvtpll_logic/mclk_asrc1	100M/24M/32K

Rockchip Confidential

Note that except for xin_osc0_func/clk_gpll_div_100m/clk_deepslow, the frequency of the other clock sources will change. Please refer to Chapter CRU for detail.
When user disables the timer enables bit (bit 0 of TIMER_TIMERn_CONTROL), the timer_en output signal is de-asserted, and timer_clk will stop. When user enables the timer, the timer_en signal is asserted and timer_clk will start running.
The application is only allowed to re-configure registers when timer_en is low.

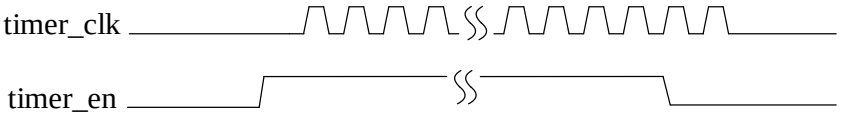

Fig. 10-2 Timing between timer_en and timer_clk

10.5.2 Programming Flow

1. Initialize the TIMER by the TIMER_TIMERn_CONTROL register:
   (1) Disable the timer by writing a "0" to the timer enable bit (bit 0). Accordingly, the timer_en output signal is de-asserted.
   (2) Program the timer mode—free-running or user-defined—by writing a "0" or "1" respectively, to the timer mode bit (bit 1).
   (3) Program the counting mode—count-up or count-down—by writing a "0" or "1" respectively to the count mode bit (bit 3).
   (4) Set the interrupt mask as either masked or not masked by writing a "0" or "1" respectively, to the timer interrupt mask bit (bit 2).
2. Load the timer count value into the TIMER_TIMERn_LOAD_COUNT1 and TIMER_TIMERn_LOAD_COUNT0 register.
3. Enable the TIMER by writing a "1" to bit 0 of TIMER_TIMERn_CONTROL.

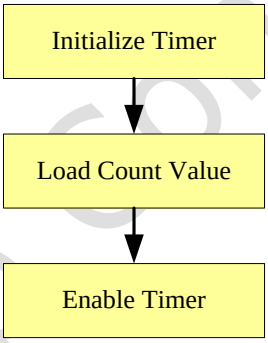

Fig. 10-3 Timer Usage Flow

Rockchip Confidential

Chapter 11 HPTIMER

11.1 Overview

HPTIMER is a programmable timer peripheral which has special calibration function. This component is an APB slave device, and can provide count value for CPU directly.

HPTIMER supports the following features:

- Support three timer mode: normal mode, hardware adjust mode and software adjust mode
- Support two counting mode at normal mode: free-running and user-defined
- Support configuration of loading count value at normal mode
- Support several mask interrupts at different timer mode
- Support calibrate back to exact count value without software calculation in hardware adjust mode
- Support calibrate back to exact count value with software-aided calculation in software adjust mode
- Support common multiple configuration of slow and fast clock period
- Support providing count value for CPU use

11.2 Block Diagram

The following figure shows the block diagram of HPTIMER:

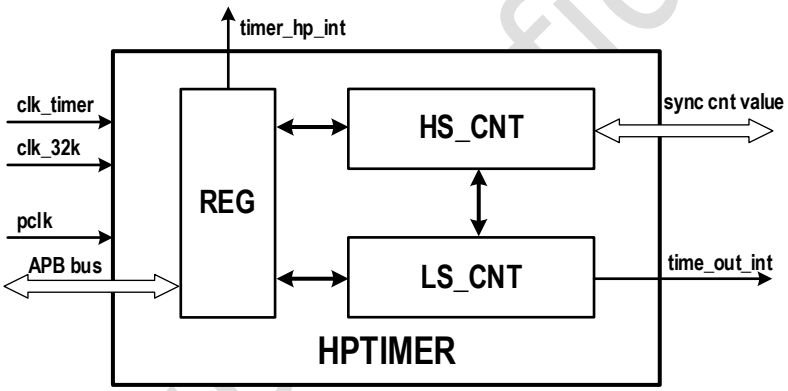

Fig. 11-1 HPTIMER Block Diagram

Register Block(REG)
This block contains several registers which are used for timer configuration, status checking and interrupt generation.
High-Speed Counter(HS_CNT)
This block contains two main counters which are working at high speed clock rate, one is used for record the current counter value that can update to CPU, the other is used to generate timing interrupt.
Low-Speed Counter(LS_CNT)
This block also contains two main counters, the different is that these counters are working at low speed clock rate, one counter is used to record the current counter value at low power mode, the other one is used as a reference counter for anti-attack.

11.3 Function Description

11.3.1 TIMER Clock

The clock frequency of clk_32k is 32KHz, and the clock frequency of clk_timer can be switched among 100MHz, 24MHz and 32KHz.

11.3.2 Timer Mode

- **Normal Mode**

At this mode, HPTIMER works as a normal incremental timer. After configuration of load count, interrupt enable, and control bit. The counter will counts from 0 to load count value step by step, and generate an interrupt when the counter value reaches the load count value. If the count mode is configured as free-running, then the counter will reload to zero,

Rockchip Confidential

after reaching the load count, and begin a new counting loop.

- **Hardware Adjust Mode**

At this mode, HPTIMER works as a special incremental timer with automatic calibration by hardware.

When system is working at normal mode, the counter in high clock domain(hs_cnt) will count up normally. And the counter in low clock domain(ls_cnt) will count plus T24_GCD every T32_GCD low clock period. Since that, the hs_cnt and the ls_cnt will represent the same counter value at every T32_GCD low clock period.

When system enter low power mode, the clock frequency of hs_cnt will also switch to low frequency, but thanks to the ls_cnt, the counter value of current time will not lost. And after system recover from low power mode, the counter value of ls_cnt will automatic calibrate to hs_cnt.

- **Software Adjust Mode**

At this mode, HPTIMER works as a special incremental timer with calibration by software. Which means software can calibrate the counter value as you wish. The hardware will record the counter value when system enter to and recover from low power mode. And software should get this two begin and end counter values to calculate the lost time during the low power mode, and make a compensation to get the correct system time.

11.4 Register Description

11.4.1 Registers Summary

Name	Offset	Size	Reset Value	Description
HPTIMER_REVISION	0x0000	W	0x2AF60201	HPTIMER Version Register

11.5 Application Notes

11.5.1 Clock and Reset

There are two different clock domains in HPTIMER: clk_timer, clk_32k. The frequency of these clocks are as below:

Table 11-1 Clock Frequency

Clock Name	Clock Source
clk_timer	100M/24M/32KHz
clk_32k	32KHz

The clock clk_timer can switch to three different frequencies according to different mode. In normal working mode, HPTIMER is working at 100MHz or 24MHz, and the exact working frequency is depending on user needs. In low power mode, HPTIMER is working at 32K. hp_sel is clock control bit to switch between 100MHz and 24MHz, which is related to CRU_PMUCLKSEL_CON00. And lp_ena is clock control bit to switch between 100M/24MHz and 32KHz, which is related to PMU_CRU_PWR_CON0[14].

Rockchip Confidential

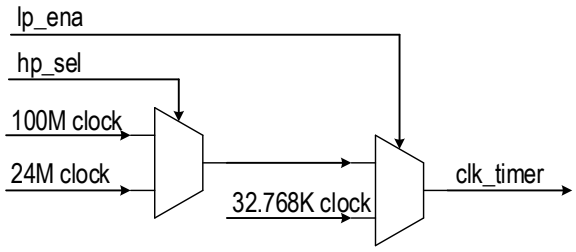

Fig. 11-2 Clock Selection of clk_timer

Please refer to chapter CRU and GRF for detail.

11.5.2 Programming Flow

- **Normal Mode**

1. Initialize the HPTIMER by the HPTIMER_CTRL register:
   (1) Disable the HPTIMER by writing a '0' to the timer enable bit (bit 0). Accordingly, the timer_hp_en output signal is de-asserted.
   (2) Program the timer mode, normal mode by writing a 0x0 to the timer mode bits (bit 1 to bit 2).
   (3) Program the count mode, free-running or user-defined by writing a '0' or '1' to the count mode bit (bit 3).
2. Load the HPTIMER count value into the HPTIMER_LOAD_COUNT1 and HPTIMER_LOAD_ COUNT0 register.
3. Enable the HPTIMER by writing a '1' to bit 0 of HPTIMER_CTRL.

If you want to do another count, repeat steps 1 to 3. These bits need to be written with the corresponding write enable bit in the higher 16 bits set to "1", as described in section 1.4.

- **Hardware Adjust Mode**

1. Initialize the HPTIMER by the HPTIMER_CTRL register:
   (1) Disable the HPTIMER by writing a '0' to the timer enable bit (bit 0). Accordingly, the timer_hp_en output signal is de-asserted.
   (2) Program the timer mode, normal mode by writing a 0x1 to the timer mode bits (bit 1 to bit 2).
   (3) Program the count mode, free-running or user-defined by writing a '0' or '1' to the count mode bit (bit 3).
2. Initialize the HPTIMER by the HPTIMER_INTR_STATUS register. Write 0x1d to HPTIMER_ INTR_STATUS register to clear HPTIMER_INTR_STATUS register.
3. Configure the HPTIMER GCD register.
   (1) Divide the least common multiple of clk_timer and clk_32k clock cycle by clk_timer clock cycle and configure it in HPTIMER_T24_GCD register.
   (2) Divide the least common multiple of clk_timer and clk_32k clock cycle by clk_32k clock cycle and configure it in HPTIMER_T32_GCD register.
4. Enable the HPTIMER by writing a '1' to bit 0 of HPTIMER_CTRL.
5. Configure the PMU_CRU_PWR_CON0 to assert lp_ena before the chip enters low power consumption mode.
6. The chip enters and exits the low power consumption mode at any time in between.
7. Configure the PMU_CRU_PWR_CON0 to de-assert lp_ena after the chip exits low power consumption mode.
8. Read out the INTR_STATUS register until the sync_done bit segment (bit 2) is '1', indicating that the HPTIMER count is adjusted.
9. Write 0x4 to HPTIMER_ INTR_STATUS register to clear HPTIMER_INTR_STATUS register.

If the chip enters and exits the low power consumption mode again, repeat steps 6 to 9. Some bits need to be written with the corresponding write enable bit in the higher 16 bits set to "1", as described in section 1.4.

- **Software Adjust Mode**

1. Initialize the HPTIMER by the HPTIMER_CTRL register:
   (1) Disable the HPTIMER by writing a '0' to the timer enable bit (bit 0). Accordingly, the timer_hp_en output signal is de-asserted.

Rockchip Confidential

(2) Program the timer mode, normal mode by writing a 0x2 to the timer mode bits (bit 1 to bit 2).
(3) Program the count mode, free-running or user-defined by writing a '0' or '1' to the count mode bit (bit 3).

2. Initialize the HPTIMER by the HPTIMER_INTR_STATUS and BEGIN_END_VALID register. Write 0x1d to HPTIMER_ INTR_STATUS register to clear HPTIMER_INTR_STATUS register. write 0x3 to RECORD_VALUE_VALID register to clear RECORD_VALUE_VALID register.
3. Enable the HPTIMER by writing a '1' to bit 0 of HPTIMER_CTRL.
4. Configure the PMU0GRF to assert lp_ena before the chip enters low power consumption mode.
5. The chip enters and exits the low power consumption mode at any time in between.
6. Configure the PMU0GRF to deassert lp_ena after the chip exits low power consumption mode.
7. Read out RECORD_VALUE_VALID register until the value of it is 0x3, which indicates that the chip has entered and exited the low power consumption mode, then you can adjust the timer count value. Then write 0x3 to RECORD_VALUE_VALID register to clear the register.
8. The count value of HPTIMER compensation.
   (1) Read out HPTIMER_T24_32BEGIN1, TIMER_ HP_T24_32BEGIN0, HPTIMER_T32_ 24END1 and HPTIMER_T32_24END0 register.
   (2) configure HPTIMER_T24_DELAT_COUNT1 and HPTIMER_T24_DELAT_COUNT0 registers to compensate for the count values according to the values of these registers read out above.
   (3) Write 0x1 to HPTIMER_SYNC_REQ register to start compensation counting.
   (4) Read out the INTR_STATUS register until the sync_done bit segment (bit 2) is '1', indicating that the compensation count is completed.
9. Write 0x5 to HPTIMER_ INTR_STATUS register to clear HPTIMER_INTR_STATUS register.

If the chip enters and exits the low power consumption mode again, repeat steps 5 to 8. Some bits need to be written with the corresponding write enable bit in the higher 16 bits set to "1", as described in section 1.4.

- **Hardware Compensation Configuration**

The hardware compensation configurations are all related to the HPTIMER_SYNC_REQ register.

1. When compensation_en(bit 4) of HPTIMER_SYNC_REQ is asserted, then the hardware will record the value of hs_cnt and ls_cnt at the time that system enters low power mode, and the record value will be stored at HPTIMER_CURR_COMP_*_32K_VALUE.
2. When low_power_compensation_en(bit 5) of HPTIMER_SYNC_REQ is asserted, then the hardware will compare the value of hs_cnt and ls_cnt at the time that system enters low power mode. And if hs_cnt is greater than ls_cnt at this time, the different will be compensated to ls_cnt.
3. When hw_sync_compensation_en(bit 6) of HPTIMER_SYNC_REQ is asserted, then the hardware will compare the value of hs_cnt and ls_cnt at the time that hardware synchronization occurs. And if hs_cnt is larger than ls_cnt at this time, the different will be compensated to ls_cnt.
4. When hw_sync_en(bit 7) of TIMRE_HP_SYNC_REQ is asserted, then the hardware will record the value of hs_cnt and ls_cnt at the time that hardware synchronization occurs, and the record value will be stored at HPTIMER_CURR_COMP_*_VALUE. The other hand, if the value of hs_cnt is greater than ls_cnt，then the synchronization to hs_cnt will not be executed.
5. When hw_sync_disable(bit 8) of HPTIMER_SYNC_REQ is asserted, then no matter the value of hs_cnt and ls_cnt, the synchronization will not be executed.

- **Low Power Mode Wakeup**

This function is used at hardware adjust mode, the programing flow is mainly as hardware adjust mode.

1. Configure HPTIMER to hardware adjust mode.

Rockchip Confidential

2. Configure the HPTIMER GCD register.
3. Enable the HPTIMER by writing a '1' to bit 0 of HPTIMER_CTRL.
4. Prepare to enter low power mode:
   (1) Configure PMU to set HPTIMER as wake up source.
   (2) Configure the bit 3 of HPTIMER_INTR_EN to set count reach interrupt enable at 32K.
   (3) Configure the HPTIMER_LOAD_COUNT1_32K and HPTIMER_LOAD_COUNT0_32K to set the wake up time. (note that user must configure HPTIMER_LOAD_COUNT0_32K at last)
5. Configure the PMU0GRF to assert lp_ena before the chip enters low power consumption mode.
6. Wait for HPTIMER to wake up system.
7. Configure the PMU0GRF to de-assert lp_ena after the chip exits low power consumption mode.
8. Read out the INTR_STATUS register and write 0x8 to HPTIMER_INTR_STATUS register to clear count reach 32k interrupt.
9. Read out the INTR_STATUS register until the sync_done bit segment (bit 2) is '1', indicating that the HPTIMER count is adjusted.
10. Write 0x4 to HPTIMER_ INTR_STATUS register to clear HPTIMER_INTR_STATUS register.

If the chip enters and exits the low power consumption mode again, repeat steps 4 to 10.

- **High Performance Timing Interrupt**

HPTIMER provides a 32-bits High performance counter to generate timing interrupt at hardware adjust mode.

1. Configure HPTIMER to hardware adjust mode.
2. Configure the HPTIMER_LOAD_COUNT0 to set the load count.
3. Configure bit 4 of HPTIMER_INTR_EN to enable interrupt.
4. Configure bit 5 of HPTIMER_CTRL to enable the hyper performance counter to work.
5. Wait for the interrupt generate.
6. Write '1' to bit 4 of HPTIMER_INTR_STATUS to clear the interrupt status.

When the count mode of timer is configured to free-running, then the interrupt will assert every load count time, otherwise the interrupt will generate only one time.

Rockchip Confidencial

Chapter 12 Watchdog Timer (WDT)

12.1 Overview

Watchdog Timer (WDT) is an APB slave peripheral that can be used to prevent system lockup that caused by conflicting parts or programs in a SOC. The WDT would generate interrupt or reset signal when its counter reaches zero, then a reset controller would reset the system.

WDT supports the following features:

- 32 bits APB bus width
- WDT counter's clock can be chosen from 24MHz or 32KHz clock
- 32 bits WDT counter width
- Counter counts down from a preset value to 0 to indicate the occurrence of a timeout
- WDT can perform two types of operations when timeout occurs:
  - Generate a system reset
  - First generate an interrupt and if this is not cleared by the service routine by the time a second timeout occurs then generate a system reset
- Programmable reset pulse length
- Total 16 defined ranges of main timeout period
- There are 2 WDTs: WDT0/1
- All the 2 WDTs can drive CRU to generate global software reset

12.2 Block Diagram

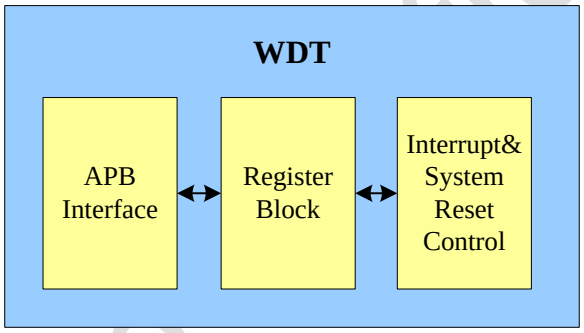

Fig. 12-1 WDT Block Diagram

WDT comprises with:

- APB Interface

The APB Interface implements the APB slave operation. Its data bus width is 32 bits.

- Register Block

A register block that read coherence for the current count register.

- Interrupt & System Reset Control

An interrupt/system reset generation block is comprised of a decrementing counter and control logic.

12.3 Function Description

12.3.1 Operation

Counter

The WDT counts from a preset (timeout) value in descending order to zero. When the counter reaches zero, depending on the output response mode selected, either a system reset or an interrupt occurs. When the counter reaches zero, it wraps to the selected timeout value and continues decrementing. The user can restart the counter to its initial value. This is programmed by writing to the restart register at any time. The process of restarting the watchdog counter is sometimes referred as kicking the dog. As a safety feature to prevent accidental restarts, the value 0x76 must be written to the Current Counter Value Register (WDT_CRR).

Interrupts

The WDT can be programmed to generate an interrupt (and then a system reset) when a

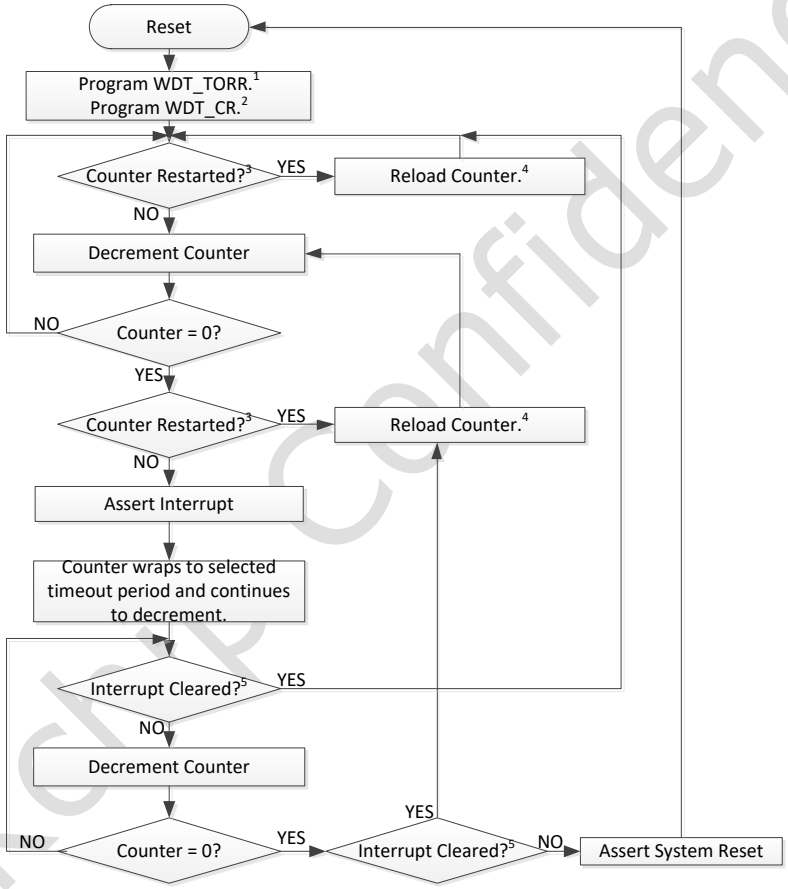

Rockchip Confidential

timeout occurs. When a 1 is written to the response mode field (RMOD, bit 1) of the Watchdog Timer Control Register (WDT_CR), the WDT generates an interrupt. If it is not cleared by the time a second timeout occurs, then it generates a system reset. If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.

System Resets
When a 0 is written to the output response mode field (RMOD, bit 1) of the Watchdog Timer Control Register (WDT_CR), the WDT generates a system reset when a timeout occurs.

Reset Pulse Length
The reset pulse length is the number of APB clock cycles for which a system reset is asserted. When a system reset is generated, it remains asserted for the number of cycles specified by the reset pulse length or until the system is reset. A counter restart has no effect on the system reset once it has been asserted.

12.3.2 Programming Sequence

1. Select required timeout period.
2. Set reset pulse length, response mode, and enable WDT.
3. Write 0x76 to WDT_CRR.
4. Starts back to selected timeout period.
5. Can clear by reading WDT_EOI or restarting (kicking) the counter by writing 0x76 to WDT_CRR.

Fig. 12-2 WDT Operation Flow (RMOD=1)

12.4 Register Description

12.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
WDT0	0xFF260000
WDT1	0xFF268000

Rockchip Confidencial

12.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description

WDT_TORR	0x0004	W	0x00000000	Timeout Range Register
WDT_CCVR	0x0008	W	0x0000FFFF	Current Counter Value Register
WDT_CRR	0x000C	W	0x00000000	Counter Restart Register
WDT_STAT	0x0010	W	0x00000000	Interrupt Status Register
WDT_EOI	0x0014	W	0x00000000	Interrupt Clear Register

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

12.4.3 Detail Registers Description

WDT_CR

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4:2	RW	0x2	rst_pluse_length This is used to select the number of APB clock cycles for which the system reset stays asserted. 3'b000: 2 pclk cycles 3'b001: 4 pclk cycles 3'b010: 8 pclk cycles 3'b011: 16 pclk cycles 3'b100: 32 pclk cycles 3'b101: 64 pclk cycles 3'b110: 128 pclk cycles 3'b111: 256 pclk cycles
1	RW	0x0	resp_mode Selects the output response generated to a timeout. 1'b0: Generate a system reset. 1'b1: First generate an interrupt and if it is not cleared by the time a second timeout occurs then generate a system reset.
0	RW	0x0	en This bit is used to enable and disable the WDT. When disabled, the counter does not decrement. Thus, no interrupt or system reset are generated. Once this bit has been enabled, it can be cleared only by a system reset. 1'b0: WDT disabled. 1'b1: WDT enabled.

WDT_TORR

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	timeout_period This field is used to select the timeout period from which the watchdog counter restarts. A change of the timeout period takes effect only after the next counter restart (kick). The range of values available for a 32-bit watchdog counter are: 4'b0000: 0x0000ffff 4'b0001: 0x0001ffff 4'b0010: 0x0003ffff 4'b0011: 0x0007ffff 4'b0100: 0x000fffff 4'b0101: 0x001fffff 4'b0110: 0x003fffff

Rockchip Confidential

Bit	Attr	Reset Value	Description
			4'b0111: 0x007fffff 4'b1000: 0x00ffffff 4'b1001: 0x01ffffff 4'b1010: 0x03ffffff 4'b1011: 0x07ffffff 4'b1100: 0x0fffffff 4'b1101: 0x1fffffff 4'b1110: 0x3fffffff 4'b1111: 0x7fffffff

WDT_CCVR

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:0	RO	0x0000ffff	cur_cnt This register, when read, is the current value of the internal counter. This value is read coherently whenever it is read.

WDT_CRR

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	WO	0x00	cnt_restart This register is used to restart the WDT counter. As a safety feature to prevent accidental restarts, the value 0x76 must be written. A restart also clears the WDT interrupt. Reading this register returns zero.

WDT_STAT

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RO	0x0	status This register shows the interrupt status of the WDT. 1'b1: Interrupt is active regardless of polarity. 1'b0: Interrupt is inactive.

WDT_EOI

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RO	0x0	int_clr This can be used to clear the interrupt without restarting the watchdog counter.

Rockchip Confidential

Chapter 13 Mailbox

13.1 Overview

The Mailbox module is a simple APB peripheral that allows MCU and CPU to communicate with each other by writing operation to generate interrupt. The registers are accessible via APB interface.
The Mailbox has the following main features:

- Support APB interface
- Support 4 mailbox groups, each group includes one data word, one command word register and one flag bit that can represent one interrupt
- Support interrupts to MCU and CPU
- Support two type of interrupt: TX done and RX done
- Support two trigger mode for TX done interrupt

13.2 Block Diagram

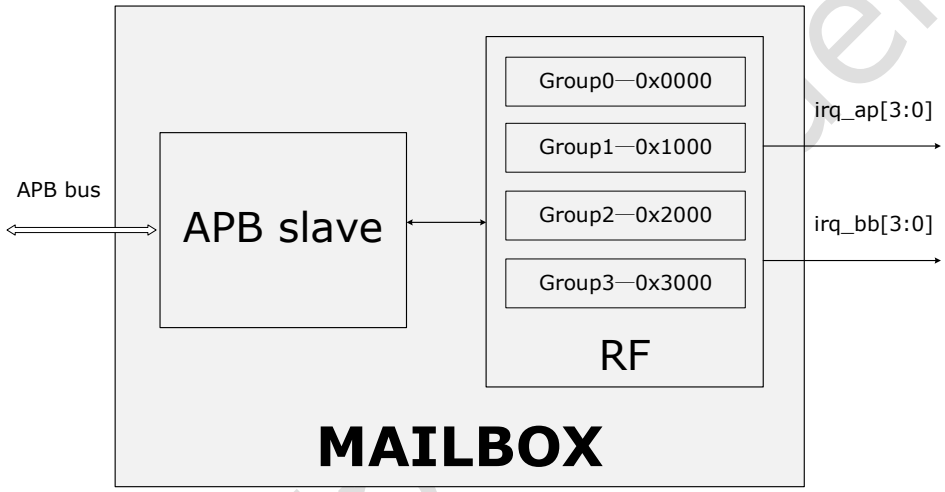

Fig. 13-1 Mailbox Block Diagram

13.3 Function Description

13.3.1 TX Done Interrupt

- Regard CPU as the "AP" side of the Mailbox. The 4 groups TX done interrupt to CPU is:
  - Enabled when MAILBOX_B2A_INTEN.b2a_tx_done_inten is set to 1 and the corresponding IRQ is enabled in GIC of CPU.
  - Generated when
    - there are writing operation to corresponding MAILBOX_B2A_CMD_i and MAILBOX_B2A_DAT_i orderly in normal mode.
    - there are writing operation to corresponding MAILBOX_B2A_CMD_i in fast trigger mode.
  - Cleared when writing 1 to corresponding MAILBOX_B2A_STATUS.b2a_tx_done_int.
- Regard MCU as the "BB" side of the Mailbox. The 4 groups TX done interrupt to MCU is:
  - Enabled when MAILBOX_A2B_INTEN.a2b_tx_done_inten is set to 1 and the corresponding IRQ is enabled in INTC of MCU.
  - Generated when
    - there are writing operation to corresponding MAILBOX_A2B_CMD_i and MAILBOX_A2B_DAT_i orderly.
    - there are writing operation to corresponding MAILBOX_A2B_CMD_i in fast

Rockchip Confidential

trigger mode.
- Cleared when writing 1 to corresponding MAILBOX_A2B_STATUS.a2b_tx_done_int.

13.3.2 RX Done Interrupt

- Regard CPU as the "AP" side of the Mailbox. The 4 groups RX done interrupt to CPU is:
  - Enabled when MAILBOX_B2A_INTEN.b2a_rx_done_inten is set to 1 and the corresponding IRQ is enabled in GIC of CPU.
  - Generated when "BB" side clear the corresponding TX done interrupt by write 1 to MAILBOX_A2B_STATUS.a2b_tx_done_int.
  - Cleared when writing 1 to the corresponding MAILBOX_B2A_STATUS.b2a_rx_done_int.
- Regard MCU as the "BB" side of the Mailbox. The 4 groups RX done interrupt to MCU is:
  - Enabled when MAILBOX_A2B_INTEN.a2b_rx_done_inten is set to 1 and the corresponding IRQ is enabled in INTC of MCU.
  - Generated when "AP" side clear the corresponding TX done interrupt by write 1 to MAILBOX_B2A_STATUS.b2a_tx_done_int.
  - Cleared when writing 1 to the corresponding MAILBOX_A2B_STATUS.a2b_rx_done_int.

- You can also regard CPU as the "BB" side of the Mailbox and regard MCU as the "AP" side of the Mailbox. The configuration flow is similar.
- Note that there are two ways for MAILBOX's interrupt to reach the MCU:
  - The interrupt is sent to the MCU through INTMUX, which needs to be configured accordingly. For details, see Cortex-M0 Chapter.
  - Interrupts are sent to the MCU via the GRF-controlled mux by selecting 1 of 8 (four interrupts each for AP and BB). For details, see SOC_CON13 in the General Register Files (GRF) Chapter.

13.4 Register Description

13.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
MAILBOX_CH0	0xFF290000
MAILBOX_CH1	0xFF291000
MAILBOX_CH2	0xFF292000
MAILBOX_CH3	0xFF293000

13.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
MAILBOX_A2B_INTEN	0x0000	W	0x00000100	AP to BB Interrupt Enable Register for Groupx
MAILBOX_A2B_STATUS	0x0004	W	0x00000000	AP to BB Interrupt Status Register for Groupx
MAILBOX_A2B_CMD	0x0008	W	0x00000000	AP to BB Command x Register
MAILBOX_A2B_DATA	0x000C	W	0x00000000	AP to BB Data x Register
MAILBOX_B2A_INTEN	0x0010	W	0x00000100	BB to AP Interrupt Enable Register for Groupx
MAILBOX_B2A_STATUS	0x0014	W	0x00000000	BB to AP Interrupt Status Register for Groupx
MAILBOX_B2A_CMD	0x0018	W	0x00000000	BB to AP Command x Register
MAILBOX_B2A_DATA	0x001C	W	0x00000000	BB to AP Data x Register

13.4.3 Detail Registers Description

MAILBOX_A2B_INTEN

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for low bit 1'b0: Disable 1'b1: Enable
15:9	RO	0x00	reserved
8	RW	0x1	a2b_trig_modex Interrupt trigger mode for a2b_tx_done_int of groupx. 1'b0: Write CMD then generate interrupt 1'b1: Write CMD firstly, then Write DATA, and then generate interrupt
7:2	RO	0x00	reserved
1	RW	0x0	a2b_rx_done_inten Interrupt enable for a2b_rx_done_int of groupx. 1'b0: Disable 1'b1: Enable
0	RW	0x0	a2b_tx_done_inten Interrupt enable for a2b_tx_done_int of groupx. 1'b0: Disable 1'b1: Enable

MAILBOX_A2B_STATUS

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	W1C	0x0	a2b_rx_done_int AP rx_done interrupt status of groupx. This interrupt will be set when AP clear the b2a_tx_done_int, and can be used to inform BB that the next message can be sent by BB. Clear the interrupt by writing 1 to this bit. 1'b0: Interrupt is inactive 1'b1: Interrupt is active
0	W1C	0x0	a2b_tx_done_int AP tx_done interrupt status of groupx. This interrupt will be set when AP write to A2B_CMD at fast trigger mode or when AP write to A2B_DATA at normal trigger mode. This interrupt can be used to inform BB that the new message from AP is ready. Clear the interrupt by writing 1 to this bit. 1'b0: Interrupt is inactive 1'b1: Interrupt is active

MAILBOX_A2B_CMD

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	command Command x register

MAILBOX_A2B_DATA

Address: **Operational Base** + offset (0x000C)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	data Data x register

MAILBOX_B2A_INTEN

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for low bit 1'b0: Disable 1'b1: Enable
15:9	RO	0x00	reserved
8	RW	0x1	b2a_trig_modex Interrupt trigger mode for b2a_tx_done_int of groupx. 1'b0: Write CMD then generate interrupt 1'b1: Write CMD firstly, then Write DATA, and then generate interrupt
7:2	RO	0x00	reserved
1	RW	0x0	b2a_rx_done_inten Interrupt enable for b2a_rx_done_int of groupx. 1'b0: Disable 1'b1: Enable
0	RW	0x0	b2a_tx_done_inten Interrupt enable for b2a_tx_done_int of groupx. 1'b0: Disable 1'b1: Enable

MAILBOX_B2A_STATUS

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	W1C	0x0	b2a_rx_done_int BB rx_done interrupt status of groupx. This interrupt will be set when BB clear the a2b_tx_done_int, and can be used to inform AP that the next message can be sent. Clear the interrupt by writing 1 to this bit. 1'b0: Interrupt is inactive 1'b1: Interrupt is active
0	W1C	0x0	b2a_tx_done_int BB tx_done interrupt status of groupx. This interrupt will be set when BB write to B2A_CMD at fast trigger mode or when BB write to B2A_DATA at normal trigger mode. This interrupt can be used to inform AP that the new message from BB is ready. Clear the interrupt by writing 1 to this bit. 1'b0: Interrupt is inactive 1'b1: Interrupt is active

MAILBOX_B2A_CMD

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	command Command x register

MAILBOX_B2A_DATA

Rockchip Confidential

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	data Data x register

13.5 Application Notes

- TX done interrupt is usually used to inform the receiver that the CMD and DATA is ready. It supports two trigger mode:
  - Normal mode
    1. Configure bit 8 of MAILBOX_*_INTEN to '1'(* stands for "A2B" or "B2A")
    2. Configure bit 0 of MAILBOX_*_INTEN to '1'
    3. Write the MAILBOX_*_CMD firstly
    4. Then write the MAILBOX_*_DATA
    5. And then generate a TX done interrupt

    Write to the MAILBOX_*_CMD register before writing to the MAILBOX_*_DATA register. If wrong order is used, then the interrupt cannot be generated successfully.
  - Fast trigger mode
    1. Configure bit 8 of MAILBOX_*_INTEN to '0'
    2. Configure bit 0 of MAILBOX_*_INTEN to '1'
    3. Write the MAILBOX_*_CMD
    4. And then generate a TX done interrupt
  - If you want to clear the interrupt, you can read out the MAILBOX_*_STATUS register and writing 1 to corresponding bit.
- RX done interrupt is usually used to inform the sender that the receiver has read out the CMD and DATA. It is triggered when the receiver has cleared the corresponding TX done interrupt:
  - AP to BB (assume TX done interrupt is set to normal mode)
    1. AP configure bit 1 of MAILBOX_B2A_INTEN to '1'
    2. BB configure bit 8 of MAILBOX_A2B_INTEN to '1'
    3. BB configure bit 0 of MAILBOX_A2B_INTEN to '1'
    4. AP write the MAILBOX_A2B_CMD
    5. AP write the MAILBOX_A2B_DATA
    6. Bit 0 of MAILBOX_A2B_STATUS is automatically set to '1' and TX done interrupt to BB is generated
    7. BB receive the TX done interrupt and read out the message
    8. BB write '1' to bit 0 of MAILBOX_A2B_STATUS
    9. And then bit 1 of MAILBOX_B2A_STATUS is automatically set to '1' and RX done interrupt to AP is generated
    10. AP receive the RX done interrupt which indicate BB has read out the message
    11. AP write '1' to bit 1 of MAILBOX_B2A_STATUS
    12. AP can start a new transfer

Rockchip Confidential

Chapter 14 SARADC

14.1 Overview

The ADC is a 4-channel single-ended 10-bit Successive Approximation Register (SAR) A/D Converter. It uses the supply and ground as its reference which avoids the use of any external reference. The input range is typically 0V to 1.8V.
SARADC controller supports the following features:

- Support single mode and series conversion mode
- In single mode, the conversion operates once each software is accessed
- In series conversion, the controller samples each channel then loops until the software stops conversion
- High/low threshold can be set, higher/lower/between high-low-threshold interrupt can be enabled

14.2 Block Diagram

SARADC block is shown in Fig. 14-1. This includes:

- APB Interface
- Control FSM
- SARADC PHY

The software can configure the SARADC controller by APB interface, then the inter FSM will communicate with SARADC PHY for limited timing requests.

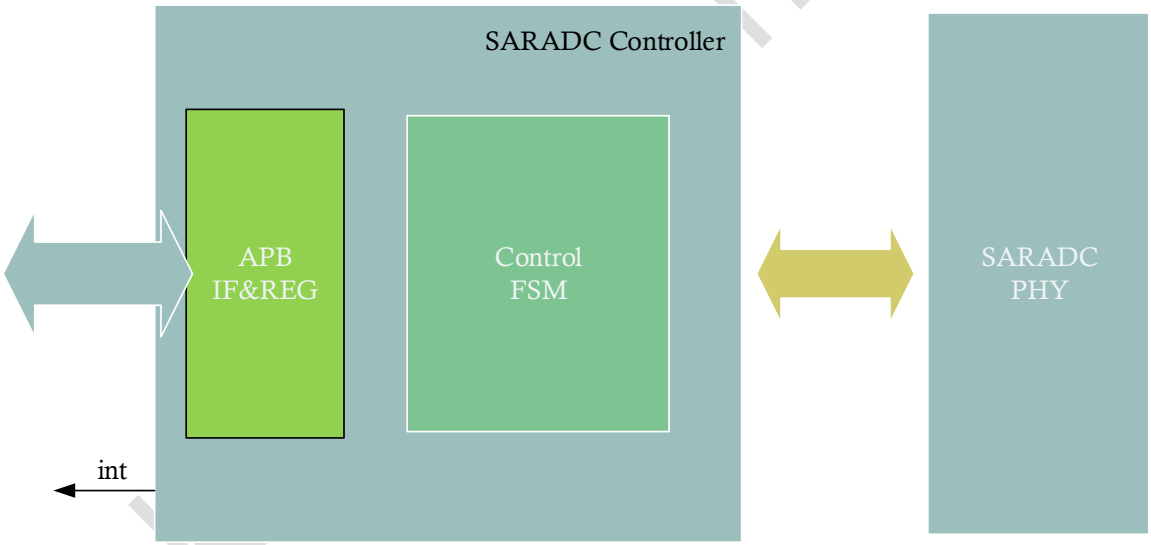

Fig. 14-1 SARADC Block Diagram

14.3 Function Description

SARADC block includes controller and PHY, user cannot directly access SARADC PHY. Software access the SARADC through SARADC controller by APB interface. SARADC controller will sample the conversion result from SARADC PHY.

14.4 Register Description

14.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

14.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
SARADC_CONV_CON	0x0000	W	0x00000000	Conversion control

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
SARADC_T_PD_SOC	0x0004	W	0x00000013	Timing control for PD to SOC
SARADC_T_AS_SOC	0x0008	W	0x00000005	Timing control for assert SOC
SARADC_T_DAS_SOC	0x000C	W	0x00000007	Timing control from dis-assert SOC to change channel
SARADC_T_SEL_SOC	0x0010	W	0x00000003	Timing control from change channel select to assert SOC
SARADC_HIGH_COMP0	0x0014	W	0x00000000	High threshold for ADC output data
SARADC_HIGH_COMP1	0x0018	W	0x00000000	High threshold for ADC output data
SARADC_HIGH_COMP2	0x001C	W	0x00000000	High threshold for ADC output data
SARADC_HIGH_COMP3	0x0020	W	0x00000000	High threshold for ADC output data
SARADC_LOW_COMP0	0x0054	W	0x00000000	Low threshold for ADC output data
SARADC_LOW_COMP1	0x0058	W	0x00000000	Low threshold for ADC output data
SARADC_LOW_COMP2	0x005C	W	0x00000000	Low threshold for ADC output data
SARADC_LOW_COMP3	0x0060	W	0x00000000	Low threshold for ADC output data
SARADC_DEBOUNCE	0x0094	W	0x00000003	Threshold debounce
SARADC_HT_INT_EN	0x0098	W	0x00000000	High threshold int enable
SARADC_LT_INT_EN	0x009C	W	0x00000000	Low threshold int enable
SARADC_MT_INT_EN	0x0100	W	0x00000000	Middle threshold int enable
SARADC_END_INT_EN	0x0104	W	0x00000000	End conversion int enable
SARADC_ST_CON	0x0108	W	0x0000001C	ADC static control
SARADC_STATUS	0x010C	W	0x00000002	ADC status
SARADC_END_INT_ST	0x0110	W	0x00000000	End conversion int state
SARADC_HT_INT_ST	0x0114	W	0x00000000	High threshold int state
SARADC_LT_INT_ST	0x0118	W	0x00000000	Low threshold int state
SARADC_MT_INT_ST	0x011C	W	0x00000000	Middle threshold int state
SARADC_DATA0	0x0120	W	0x00000000	ADC output data
SARADC_DATA1	0x0124	W	0x00000000	ADC output data
SARADC_DATA2	0x0128	W	0x00000000	ADC output data
SARADC_DATA3	0x012C	W	0x00000000	ADC output data
SARADC_AUTO_CH_EN	0x0160	W	0x00000000	Channel enable in auto channel mode

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

14.4.3 Detail Registers Description

SARADC_CONV_CON

Address: Operational Base(0xFF4E8000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:10	RO	0x00	reserved
9	RW	0x0	int_lock This is used to lock the sample data when interrupt happened. 1'b0: Disable lock 1'b1: Enable lock

Rockchip Confidential

Bit	Attr	Reset Value	Description
8	RW	0x0	as_pd_mode If this bit is set to 1'b1, each time conversion ends, PD will be asserts. Then next time conversion starts, PD will be set to low automatically. This is not used in signal mode.
7	W1C	0x0	end_conv End conversion, this is not used when CONV_CON[5] is set to 1'b1. If this bit set to 1'b1, PD will set to 1'b1 after the last conversion and this bit will be cleared to 1'b0.
6	RW	0x0	auto_channel_mode Auto channel mode. If this is enable, channel will be round auto according which is set in AUTO_CH_EN.
5	RW	0x0	single_pd_mode Single conversion mode. If this bit is set to 1, conversion only operate once, then PD single will be set to 1.
4	W1C	0x0	start_adc Enable ADC, if this bit set to one, conversion will start. Then this bit will be clear to 0.
3:0	RW	0x0	channel_sel Channel for SARADC, 4 channel is supported. This field is not used when CONV_CON[6] is set to 1. 4'd0: Select channel 0 4'd1: Select channel 1 4'd2: Select channel 2 4'd3: Select channel 3

SARADC_T_PD_SOC

Address: Operational Base(0xFF4E8000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x13	t_pd_soc Timing control between power up to start-of-conversion.

SARADC_T_AS_SOC

Address: Operational Base(0xFF4E8000) + offset (0x0008)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000005	t_as_soc Timing control for assert SOC signal.

SARADC_T_DAS_SOC

Address: Operational Base(0xFF4E8000) + offset (0x000C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000007	t_das_soc Timing from dis-assert SOC to channel select change.

SARADC_T_SEL_SOC

Address: Operational Base(0xFF4E8000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0003	t_sel_soc Timing from channel load to SOC assert.

SARADC_HIGH_COMP0

Address: Operational Base(0xFF4E8000) + offset (0x0014)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	high_comp0 High threshold for ADC output data for channel 0.

SARADC_HIGH_COMP1

Address: Operational Base(0xFF4E8000) + offset (0x0018)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	high_comp1 High threshold for ADC output data for channel 1.

SARADC_HIGH_COMP2

Address: Operational Base(0xFF4E8000) + offset (0x001C)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	high_comp2 High threshold for ADC output data for channel 2.

SARADC_HIGH_COMP3

Address: Operational Base(0xFF4E8000) + offset (0x0020)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	high_comp3 High threshold for ADC output data for channel 3.

SARADC_LOW_COMP0

Address: Operational Base(0xFF4E8000) + offset (0x0054)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	low_comp0 Low threshold for ADC output data for channel 0.

SARADC_LOW_COMP1

Address: Operational Base(0xFF4E8000) + offset (0x0058)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	low_comp1 Low threshold for ADC output data for channel 1.

SARADC_LOW_COMP2

Address: Operational Base(0xFF4E8000) + offset (0x005C)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	low_comp2 Low threshold for ADC output data for channel 2.

SARADC_LOW_COMP3

Address: Operational Base(0xFF4E8000) + offset (0x0060)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	low_comp3 Low threshold for ADC output data for channel 3.

SARADC_DEBOUNCE

Rockchip Confidential

Address: Operational Base(0xFF4E8000) + offset (0x0094)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x03	debounce ADC controller will only generate interrupt data is higher/lower/between setting threshold for "debounce" times.

SARADC_HT_INT_EN

Address: Operational Base(0xFF4E8000) + offset (0x0098)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:4	RO	0x0	reserved
3	RW	0x0	ht_int_en3 High threshold interrupt for channel 3. 1'b0: Disable interrupt 1'b1: Enable interrupt
2	RW	0x0	ht_int_en2 High threshold interrupt for channel 2. 1'b0: Disable interrupt 1'b1: Enable interrupt
1	RW	0x0	ht_int_en1 High threshold interrupt for channel 1. 1'b0: Disable interrupt 1'b1: Enable interrupt
0	RW	0x0	ht_int_en0 High threshold interrupt for channel 0. 1'b0: Disable interrupt 1'b1: Enable interrupt

SARADC_LT_INT_EN

Address: Operational Base(0xFF4E8000) + offset (0x009C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:4	RO	0x0	reserved
3	RW	0x0	lt_int_en3 Low threshold interrupt for channel 3. 1'b0: Disable interrupt 1'b1: Enable interrupt
2	RW	0x0	lt_int_en2 Low threshold interrupt for channel 2. 1'b0: Disable interrupt 1'b1: Enable interrupt
1	RW	0x0	lt_int_en1 Low threshold interrupt for channel 1. 1'b0: Disable interrupt 1'b1: Enable interrupt
0	RW	0x0	lt_int_en0 Low threshold interrupt for channel 0. 1'b0: Disable interrupt 1'b1: Enable interrupt

Rockchip Confidencial

SARADC_MT_INT_EN

Address: Operational Base(0xFF4E8000) + offset (0x0100)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:4	RO	0x0	reserved
3	RW	0x0	mt_int_en3 Middle threshold interrupt for channel3. 1'b0: Disable interrupt 1'b1: Enable interrupt
2	RW	0x0	mt_int_en2 Middle threshold interrupt for channel2. 1'b0: Disable interrupt 1'b1: Enable interrupt
1	RW	0x0	mt_int_en1 Middle threshold interrupt for channel1. 1'b0: Disable interrupt 1'b1: Enable interrupt
0	RW	0x0	mt_int_en0 Middle threshold interrupt for channel0. 1'b0: Disable interrupt 1'b1: Enable interrupt

SARADC_END_INT_EN

Address: Operational Base(0xFF4E8000) + offset (0x0104)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:1	RO	0x0000	reserved
0	RW	0x0	end_int_en End of conversion interrupt. 1'b0: Disable end conversion interrupt 1'b1: Enable end conversion interrupt

SARADC_ST_CON

Address: Operational Base(0xFF4E8000) + offset (0x0108)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:3	RW	0x3	ictrl Control the bias current of the preamplifier in the SAR-ADC.
2:0	RW	0x4	cctrl Control the capacitance of the capacitor DAC array, which is related to the linearity of the SAR-ADC.

SARADC_STATUS

Address: Operational Base(0xFF4E8000) + offset (0x010C)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:2	RO	0x0	sel ADC channel select

Rockchip Confidencial

Bit	Attr	Reset Value	Description
1	RO	0x1	pd 1'b1: ADC is power down. 1'b0: ADC is power up and in conversion.
0	RO	0x0	conv_st Conversion status 1'b1: ADC controller FSM is busy. 1'b0: ADC controller FSM is idle.

SARADC_END_INT_ST

Address: Operational Base(0xFF4E8000) + offset (0x0110)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	W1C	0x0	end_int_st ADC end conversion interrupt status. 1'b0: Interrupt not happened 1'b1: Interrupt happened

SARADC_HT_INT_ST

Address: Operational Base(0xFF4E8000) + offset (0x0114)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000	reserved
3	W1C	0x0	ht_int_st3 High threshold interrupt state for channel 3. 1'b0: Interrupt not happened 1'b1: Interrupt happened
2	W1C	0x0	ht_int_st2 High threshold interrupt state for channel 2. 1'b0: Interrupt not happened 1'b1: Interrupt happened
1	W1C	0x0	ht_int_st1 High threshold interrupt state for channel 1. 1'b0: Interrupt not happened 1'b1: Interrupt happened
0	W1C	0x0	ht_int_st0 High threshold interrupt state for channel 0. 1'b0: Interrupt not happened 1'b1: Interrupt happened

SARADC_LT_INT_ST

Address: Operational Base(0xFF4E8000) + offset (0x0118)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000	reserved
3	W1C	0x0	lt_int_st3 Low threshold interrupt state for channel 3. 1'b0: Interrupt not happened 1'b1: Interrupt happened
2	W1C	0x0	lt_int_st2 Low threshold interrupt state for channel 2. 1'b0: Interrupt not happened 1'b1: Interrupt happened
1	W1C	0x0	lt_int_st1 Low threshold interrupt state for channel 1. 1'b0: Interrupt not happened 1'b1: Interrupt happened

Rockchip Confidencial

Bit	Attr	Reset Value	Description
0	W1C	0x0	lt_int_st0 Low threshold interrupt state for channel 0. 1'b0: Interrupt not happened 1'b1: Interrupt happened

SARADC_MT_INT_ST

Address: Operational Base(0xFF4E8000) + offset (0x011C)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000	reserved
3	W1C	0x0	mt_int_st3 Between high and low threshold interrupt state for channel 3. 1'b0: Interrupt not happened 1'b1: Interrupt happened
2	W1C	0x0	mt_int_st2 Between high and low threshold interrupt state for channel 2. 1'b0: Interrupt not happened 1'b1: Interrupt happened
1	W1C	0x0	mt_int_st1 Between high and low threshold interrupt state for channel 1. 1'b0: Interrupt not happened 1'b1: Interrupt happened
0	W1C	0x0	mt_int_st0 Between high and low threshold interrupt state for channel 0. 1'b0: Interrupt not happened 1'b1: Interrupt happened

SARADC_DATA0

Address: Operational Base(0xFF4E8000) + offset (0x0120)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RO	0x000	data0 ADC channel 0 data

SARADC_DATA1

Address: Operational Base(0xFF4E8000) + offset (0x0124)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RO	0x000	data1 ADC channel 1 data

SARADC_DATA2

Address: Operational Base(0xFF4E8000) + offset (0x0128)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RO	0x000	data2 ADC channel 2 data

SARADC_DATA3

Address: Operational Base(0xFF4E8000) + offset (0x012C)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RO	0x000	data3 ADC channel 3 data

SARADC_AUTO_CH_EN

Rockchip Confidential

Address: Operational Base(0xFF4E8000) + offset (0x0160)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	auto_ch_en Enable channel in auto channel mode, each bit can enable for one channel.

14.5 Application Notes

14.5.1 Series Conversion Mode

Steps of ADC conversion in series conversion mode:

- Decide which channel should be used and whether auto_channel mode should be set. In auto_channel mode, the channel will be changed from 0-3 then to 0. Please refer to the SARADC_CONV_CON register.
- Set SARADC_CONV_CON[4] to 1’b1, then the conversion will start.
- If conversion wants to be ended, set SARADC_CONV_CON[7] to 1’b1.
- Conversion could be read from SARADC_DATAn (n is from 0-3).
- If threshold compare interrupt wants to be used, high/low threshold could be set, and interrupt should be set as an application.
- If auto_channel mode is not set, you could set the channel as an application.

14.5.2 Single Mode

Steps of ADC conversion in single mode:

- Decide which channel should be used and set SARADC_CONV_CON[3:0].
- Set SARADC_CONV_CON[5] to 1’b1.
- Set SARADC_CONV_CON[4] to 1’b1, then the conversion will start.
- The conversion only operates once then ends. PD will be asserted and PD status could be got by reading SARADC_STATUS.
- Conversion could be read from SARADC_DATAn (n is from 0-3).

Rockchip Confidential

Chapter 15 Temperature-Sensor ADC (TSADC)

15.1 Overview

TSADC controller is used to control and get the temperature information. TSADC will convert for each enabled channel in loop after the initial setting and can be stopped by software. If you find that the temperature is high in a period of time, an interrupt is generated to the processor down-measures taken; if the temperature over a period of time High, the resulting TSHUT gave CRU module, let it reset the entire chip, or via GPIO give PMIC. Also, if you find that the temperature low in a period of time, an interrupt can be generated.

TSADC controller supports the following features:

- The temperature for high and low interrupt can be configured
- The temperature of system reset can be configured
- The time interval of temperature detection can be configured
- When detecting a high temperature, the time interval of temperature detection can be configured
- High temperature debounce can be configured
- An interrupt can be generated after TSADC converts all setting channel
- -40~125°C temperature range and 0.6°C temperature resolution

15.2 Block Diagram

TSADC controller comprises with:

- APB Interface
- TSADC control logic

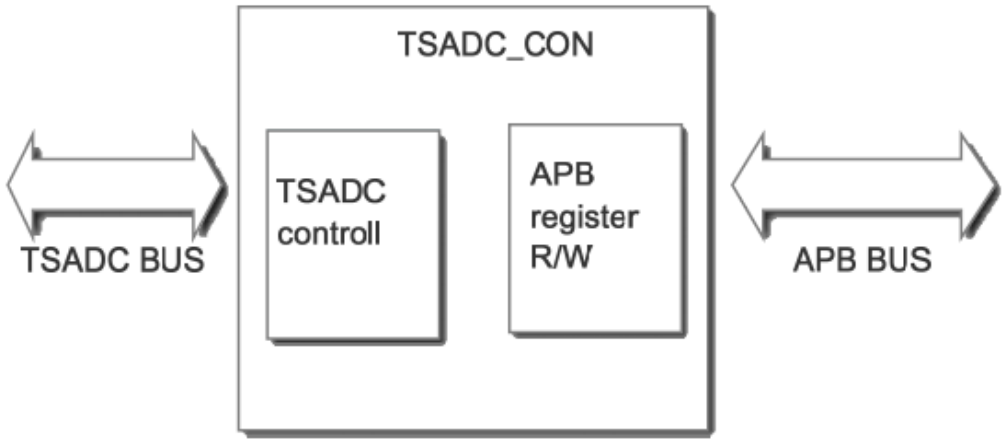

Fig. 15-1 TSADC Controller Block Diagram

15.3 Function Description

15.3.1 APB Interface

There is an APB Slave interface in TSADC controller, which is used to configure the TSADC controller registers and look up the temperature from the temperature sensor.

15.3.2 TSADC Controller

This block is used to control the TSADC PHY to meet the conversion timing and receive the temperature information from TSADC PHY.

15.4 Register Description

15.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

15.4.2 Registers Summary

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
TSADC_USER_CON	0x0000	W	0x00000000	User control
TSADC_AUTO_CON	0x0004	W	0x00000000	Auto control
TSADC_AUTO_STATUS	0x0008	W	0x00000000	Status used in auto mode
TSADC_AUTO_SRC	0x000C	W	0x00000000	Channel select for TSADC in auto mode
TSADC_LT_EN	0x0010	W	0x00000000	Low temperature check logic enable
TSADC_HT_INT_EN	0x0014	W	0x00000000	High temperature interrupt enable
TSADC_GPIO_EN	0x0018	W	0x00000000	Temperature violation to GPIO enable
TSADC_CRU_EN	0x001C	W	0x00000000	Temperature violation to CRU enable
TSADC_LT_INT_EN	0x0020	W	0x00000000	Low temperature interrupt enable
TSADC_HLT_INT_PD	0x0024	W	0x00000000	High and low temperature interrupt status
TSADC_EOC_HSHUT_PD	0x0028	W	0x00000000	High temperature shut and round int status
TSADC_DATA0	0x002C	W	0x00000000	Channel0 data
TSADC_COMP0_INT	0x006C	W	0x00000000	High temperature interrupt threshold for channel0
TSADC_COMP0_SHUT	0x010C	W	0x00000000	High temperature shut threshold for channel0
TSADC_HIGH_INT_DEBOUNCE	0x014C	W	0x00000003	High interrupt debounce
TSADC_HIGH_TSHUT_DEBOUNCE	0x0150	W	0x00000003	High shut debounce
TSADC_AUTO_PERIOD	0x0154	W	0x00010000	Auto conversion period
TSADC_AUTO_PERIOD_HT	0x0158	W	0x00010000	Auto conversion period for high temperature
TSADC_COMP0_LOW_INT	0x015C	W	0x00000000	Low temperature threshold for channel0
TSADC_T_SETUP	0x019C	W	0x0000005F	Timing for setup
TSADC_T_PW_EN	0x0200	W	0x00000000	Timing for pw_en
TSADC_T_EN_CLK	0x0204	W	0x00000001	Timing for en_clk
TSADC_T_NON_OV	0x0208	W	0x00000002	Timing for non_ov
TSADC_T_HOLD	0x020C	W	0x00000013	Timing for hold
TSADC_Q_MAX	0x0210	W	0x00000000	Max data used for data inversion
TSADC_STATIC_CON	0x0214	W	0x0280001B	Static control signal
TSADC_CLK_CH_PERIOD	0x021C	W	0x0000012B	CLK_CH_TS period control
TSADC_T_PW_CLK	0x0220	W	0x00000030	Timing for pw_clk

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

15.4.3 Detail Registers Description

TSADC_USER_CON

Address: Operational Base(0xFF650000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:9	RO	0x00	reserved
8	RO	0x0	adc_status 1'b0: ADC stop 1'b1: Conversion in progress

Rockchip Confidential

Bit	Attr	Reset Value	Description
7	R/W SC	0x0	start When software write 1 to this bit, start-of-conversion will be assert. This bit will be cleared after TSADC access finishing. Only when TSADC_USER_CON[5] = 1'b1, this bit takes effect.
6	RW	0x0	eoc_inten Enable end-of-conversion interrupt for each conversion. 1'b0 : Disable 1'b1 : Enable
5	RW	0x0	start_mode Start mode. 1'b0: TSADC controller will assert start_of_conversion after power up. 1'b1: The start_of_conversion will be controlled by TSADC_USER_CON[7].
4	RW	0x0	power_control ADC power control 1'b0: Power down 1'b1: Power up This bit is not enable when TSADC_AUTO_CON[0] is set to 1.
3:0	RW	0x0	input_src_sel ADC input source select in user mode. Should be set at 0.

TSADC_AUTO_CON

Address: Operational Base(0xFF650000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:9	RO	0x00	reserved
8	RW	0x0	tshut_polarity This bit is used to control the output signal polarity to GPIO when the temperature is higher than threshold. 1'b0: Low active 1'b1: High active
7:3	RO	0x00	reserved
2	RW	0x0	round_int_en Int enable for round mode. Used for auto mode all channel set is sampled. 1'b1: Enable 1'b0: Disable
1	RW	0x0	q_sel 1'b0: Use tsadc_q as output (positive temperature coefficient) 1'b1: Use (q_max - tsadc_q) as output (negative temperature coefficient)
0	RW	0x0	auto_en Auto conversion enable 1'b0: TSADC controller works at user-define mode 1'b1: TSADC controller works at auto mode

TSADC_AUTO_STATUS

Address: Operational Base(0xFF650000) + offset (0x0008)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3	RW	0x0	ht_wram High temperature status 1'b0: TSADC data is not higher than high temperature shut value 1'b1: TSADC data is higher than high temperature shut value
2	RW	0x0	auto_status TSADC auto mode status 1'b0: Auto mode stop 1'b1: Auto mode in progress
1	W1C	0x0	last_tshut_cru Status for CRU reset latest temperature shut, write 1 to clear.
0	W1C	0x0	last_tshut_gpio Status for GPIO latest temperature shut, write 1 to clear.

TSADC_AUTO_SRC

Address: Operational Base(0xFF650000) + offset (0x000C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:0	RW	0x0000	auto_src Enable channel for TSADC in auto mode, each bit can enable for one channel.

TSADC_LT_EN

Address: Operational Base(0xFF650000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:0	RW	0x0000	low_temperature_vio_en Low temperature violation logic enable, each bit enables one channel. 1'b1: Enable 1'b0: Disable

TSADC_HT_INT_EN

Address: Operational Base(0xFF650000) + offset (0x0014)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:0	RW	0x0000	high_temperature_int_en High temperature interrupt enable, each bit enables one channel. 1'b1: Enable 1'b0: Disable

TSADC_GPIO_EN

Address: Operational Base(0xFF650000) + offset (0x0018)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:0	RW	0x0000	gpio_en Temperature violation to GPIO enable, each bit enables one channel. 1'b1: Enable 1'b0: Disable

TSADC_CRU_EN

Address: Operational Base(0xFF650000) + offset (0x001C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:0	RW	0x0000	cru_en Temperature violation to CRU reset enable, each bit enables one channel. 1'b1: Enable 1'b0: Disable

TSADC_LT_INT_EN

Address: Operational Base(0xFF650000) + offset (0x0020)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b1: Write access enable 1'b0: Write access disable
15:0	RW	0x0000	low_temperature_int_en Low temperature interrupt enable, each bit enables one channel. 1'b1: Enable 1'b0: Disable

TSADC_HLT_INT_PD

Address: **Operational Base(0xFF650000)** + offset (0x0024)

Bit	Attr	Reset Value	Description
31:16	W1C	0x0000	lt_int_status Low temperature interrupt status for each channel.
15:0	W1C	0x0000	ht_int_status High temperature interrupt status for each channel.

TSADC_EOC_HSHUT_PD

Address: Operational Base(0xFF650000) + offset (0x0028)

Bit	Attr	Reset Value	Description
31:18	RO	0x0000	reserved
17	W1C	0x0	round_int_pd Auto mode interrupt for each round of all set channel.
16	W1C	0x0	usr_eoc_irq_pd User mode end interrupt status.
15:0	W1C	0x0000	ht_shut_pd High temperature shut down status for each channel.

TSADC_DATA0

Rockchip Confidencial

Address: Operational Base(0xFF650000) + offset (0x002C)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RO	0x000	adc_data A/D value of the channel 0 last conversion.

TSADC_COMP0_INT

Address: Operational Base(0xFF650000) + offset (0x006C)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RW	0x000	tsadc_h_int_comp_src0 TSADC high temperature level. TSADC output is bigger than or equal to this 10-bit value, means the temperature is high. TSADC_INT will be valid.

TSADC_COMP0_SHUT

Address: Operational Base(0xFF650000) + offset (0x010C)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RW	0x000	tsadc_shut_comp_src0 TSADC high temperature level. TSADC output is bigger than or equal to this 10-bit value, means the temperature is too high. TSHUT will be valid.

TSADC_HIGH_INT_DEBOUNCE

Address: Operational Base(0xFF650000) + offset (0x014C)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x03	debounce TSADC controller will only generate interrupt when temperature is higher than or equal to COMP_INT for "debounce" times.

TSADC_HIGH_TSHUT_DEBOUNCE

Address: Operational Base(0xFF650000) + offset (0x0150)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x03	debounce TSADC controller will only generate TSHUT when temperature is higher than or equal to COMP_SHUT for "debounce" times.

TSADC_AUTO_PERIOD

Address: Operational Base(0xFF650000) + offset (0x0154)

Bit	Attr	Reset Value	Description
31:0	RW	0x00010000	auto_period When auto mode is enabled, this register controls the interleave between every conversion for all channel enabled of TSADC.

TSADC_AUTO_PERIOD_HT

Address: **Operational Base(0xFF650000)** + offset (0x0158)

Bit	Attr	Reset Value	Description
31:0	RW	0x00010000	auto_period This register controls the interleave between every conversion for all channel enabled of TSADC after the temperature is higher than or equal to COMP_SHUT or COMP_INT.

Rockchip Confidencial

TSADC_COMP0_LOW_INT

Address: Operational Base(0xFF650000) + offset (0x015C)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RW	0x000	tsadc_l_int_comp_src0 TSADC low temperature level. TSADC output is lower than or equal to this 10-bit value, means the temperature is low. TSADC_LOW_INT will be valid.

TSADC_T_SETUP

Address: Operational Base(0xFF650000) + offset (0x019C)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x005f	t_setup The timing between TSADC power up and start conversion.

TSADC_T_PW_EN

Address: Operational Base(0xFF650000) + offset (0x0200)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	t_pw_en The timing assert start conversion signal.

TSADC_T_EN_CLK

Address: Operational Base(0xFF650000) + offset (0x0204)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x01	t_en_clk The timing between dis-assert start conversion signal (EN_TEMP_SEN_TS) and assert CLK_SEN_TS[8].

TSADC_T_NON_OV

Address: Operational Base(0xFF650000) + offset (0x0208)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x02	t_non_ov The timing between each bit assertion of CLK_SENSE_TS.

TSADC_T_HOLD

Address: Operational Base(0xFF650000) + offset (0x020C)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0013	t_hold The timing between dis-assert CLK_SENSE_TS and TSADC data valid.

TSADC_Q_MAX

Address: Operational Base(0xFF650000) + offset (0x0210)

Bit	Attr	Reset Value	Description
31:11	RO	0x000000	reserved
10:0	RW	0x000	q_max This register used for TSADC_AUTO_CON[1] for inversion output data.

Rockchip Confidencial

TSADC_STATIC_CON

Address: Operational Base(0xFF650000) + offset (0x0214)

Bit	Attr	Reset Value	Description
31:27	RW	0x00	buf_vref_sel Offset control for temperature output code.
26:23	RW	0x5	buf_slope_sel Slope control for temperature output code.
22:21	RW	0x0	comp_i_trim Comparator current timing ports.
20:17	RW	0x0	vbe_i_trm Current timing ports for VBE in PTAT generator.
16:13	RW	0x0	verf_trim Reference voltage trimming ports for reference generator.
12:9	RW	0x0	bgr_r_trim BGR control ports in reference generator.
8:5	RW	0x0	bgr_i_trim BJT emitter current control ports in reference generator.
4:2	RW	0x6	avg_mode Average mode control ports for digital filter.
1	RW	0x1	en_dem Dynamic element matching enable port.
0	RW	0x1	en_ch Digital offset cancellation enable port.

TSADC_CLK_CH_PERIOD

Address: Operational Base(0xFF650000) + offset (0x021C)

Bit	Attr	Reset Value	Description
31:0	RW	0x0000012b	clk_ch_period Control the period of CLK_CH_TS.

TSADC_T_PW_CLK

Address: Operational Base(0xFF650000) + offset (0x0220)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0030	t_pw_clk The timing for assertion of each bit of CLK_SENSE_TS.

15.5 Interface Description

Table 15-1 TSADC Rockchip Matrix IO Interface Description

Module Pin	Dir	Pad Name	IOMUX Setting
IOMUX0			
tsadc_tshut	O		

Notes: I=input, O=output, I/O=input/output. For the configuration of RM_IO, please refer to chapter "Rockchip Matrix IO".

15.6 Application Notes

15.6.1 Conversion Flow

The system works as follows:

1) Temperature violation and other configurations may be set.
2) Assert tsadc_tsen_en and tsadc_ana_reg0/1/2.
3) Set the bit[0] in register TSADC_AUTO_CON, then TSADC will work.
4) Then temperature information can be read from the APB interface.
5) If TSADC needs to be closed, set bit[0] in register TSADC_AUTO_CON to 1'b0.

Rockchip Confidencial

15.6.2 Timing Diagram

When TSADC start to work, the timing will follow the Fig. 15-2
The timing requirement is also listed as follows.

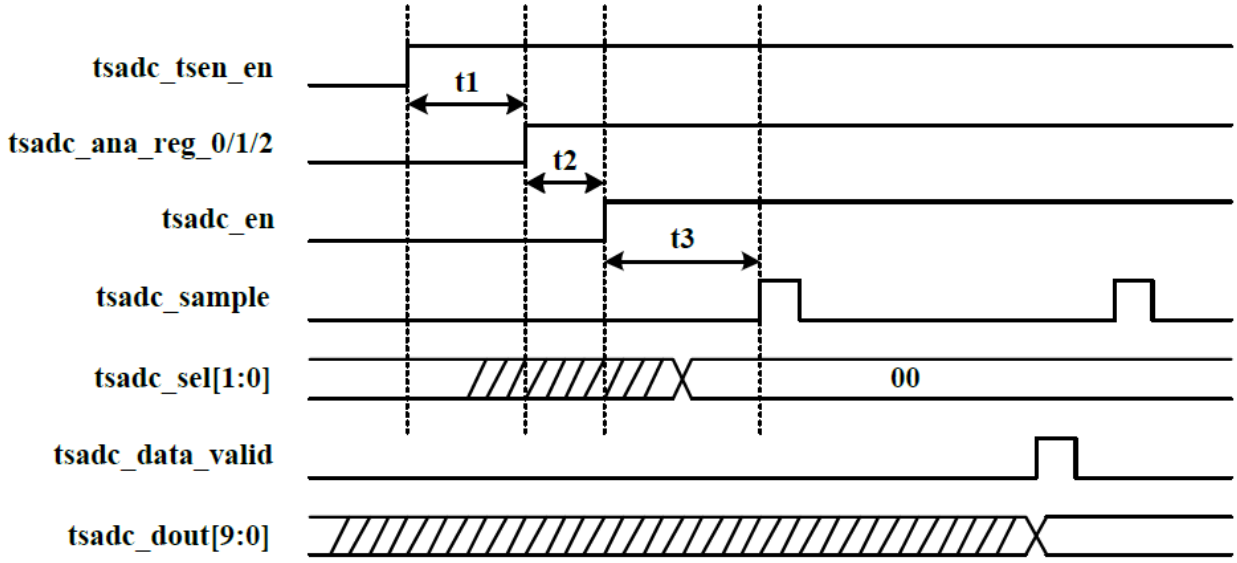

Fig. 15-2 Timing Diagram for TSADC

Table 15-2 TSADC Start Timing

parameter	min
t1	10us
t2	0us
t3	90us

15.6.3 Temperature-to-Code Mapping

Table 15-3 TSADC Lookup Table

temperature (℃)	typical output
-40	395
-35	403
-30	411
0	462
5	470
10	478
25	503
30	511
80	596
85	604
115	655
120	664
125	672

Note:
Code to Temperature mapping of the Temperature sensor is a linear curve. Any temperature, code falling between to 2 given temperatures can be linearly interpolated.
Code to Temperature mapping should be updated based on silicon results.

Rockchip Confidential

Chapter 16 SPINLOCK

16.1 Overview

The hardware spinlock used for spinlock status storage. All the CPU and MCU can access spinlock to get the lock status.

16.2 Block Diagram

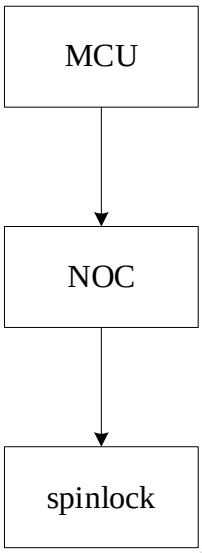

Fig.16-1 Spinlock in System

16.3 Function Description

The CPU and MCU can obtain a lock by writing a non-zero value to the SPINLOCK_STATUS_x register in the spinlock; The CPU and MCU can also read SPINLOCK_STATUS_x to query the status of the lock.

16.4 Register Description

16.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
SPINLOCK-CH0	0xFF240000
SPINLOCK-CH1	0xFF241000
SPINLOCK-CH2	0xFF242000
SPINLOCK-CH3	0xFF243000

16.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
SPINLOCK_STATUS_0	0x0000	W	0x00000000	Spinlock Status Controller Register 0
SPINLOCK_STATUS_1	0x0004	W	0x00000000	Spinlock Status Controller Register 1
SPINLOCK_STATUS_2	0x0008	W	0x00000000	Spinlock Status Controller Register 2
SPINLOCK_STATUS_3	0x000C	W	0x00000000	Spinlock Status Controller Register 3

Rockchip Confidencial

Name	Offset	Size	Reset Value	Description
SPINLOCK_STATUS_4	0x0010	W	0x00000000	Spinlock Status Controller Register 4
SPINLOCK_STATUS_5	0x0014	W	0x00000000	Spinlock Status Controller Register 5
SPINLOCK_STATUS_6	0x0018	W	0x00000000	Spinlock Status Controller Register 6
SPINLOCK_STATUS_7	0x001C	W	0x00000000	Spinlock Status Controller Register 7

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

16.4.3 Detail Registers Description

SPINLOCK_STATUS_0

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_1

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_2

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_3

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_4

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_5

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_6

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

SPINLOCK_STATUS_7

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RW	0x0	spinlock_status When 4bits is 0, 4bits can be written with new value. When 4bits is not 0, 4bits cannot be written. When write data is 4'b0000, 4bits clean to 0.

16.5 Application Notes

The spinlock can be used as follows：

Chapter 17 GPIO

17.1 Overview

GPIO is a programmable General Purpose Programming I/O peripheral. This component is an APB slave device. GPIO controls the output data and direction of external I/O pads. It can also read back the data on external pads using memory-mapped registers.
GPIO supports the following features:

- 32 bits APB data bus width
- Up to 32 independently configurable signals
- Software control registers with write mask for each bit of each signal
- Configurable debounce logic with a slow clock to debounce interrupts
- Configurable interrupt mode
- Four virtual OS with independent control registers can be supported
- In virtual OS mode, each OS has independent interrupt
- GPIO input is filtered to remove burrs. The filter function is configured using GRF

17.2 Block Diagram

GPIO is comprised of:

- APB Interface

The APB Interface implements the APB slave operation. Its data bus width is 32 bits.

- I/O Port Interface

External data interface to or from I/O pads.

- Interrupt Detection

Interrupt interface to or from interrupt controller.

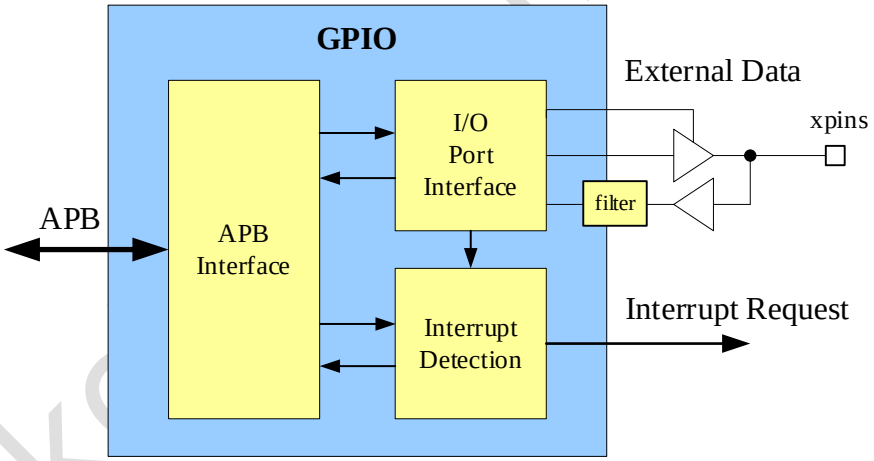

Fig. 17-1 GPIO Block Diagram

17.3 Function Description

17.3.1 Data Control

Under software control, the data and direction control for the signal are sourced from the port data registers (GPIO_SWPORT_DR_L/GPIO_SWPORT_DR_H) and direction control registers (GPIO_SWPORT_DDR_L/GPIO_SWPORT_DRR_H). The direction of the external I/O pad is controlled by the value of the port data direction registers. The data written to these memory-mapped registers gets mapped onto an output signal (gpio_port_ddr) of the GPIO peripheral. This output signal controls the direction of an external I/O pad. The default data direction is Input. The data written to the port data registers drives the output buffer (gpio_port_dr) of the I/O pad.

External data are input on the external data signal (gpio_ext_port). Reading the external signal register (GPIO_EXT_PORT) shows the value of this signal, regardless of the direction.

Rockchip Confidencial

This register is read-only, meaning that it cannot be written from the APB software interface.

17.3.2 Interrupts

I/O port can be programmed to accept external signals as interrupt sources on any of the bits of the signal. The type of interrupt is programmable with one of the following settings:

- Active-high and level
- Active-low and level
- Rising edge
- Falling edge
- Both the rising edge and the falling edge

The interrupts can be masked by programming the GPIO_INT_MASK_L/GPIO_INT_MASK_H registers. The interrupt status can be read before masking (GPIO_INT_RAWSTATUS) and after masking (GPIO_INT_STATUS).

For edge-sensitive interrupts, the Interrupt Service Routine (ISR) can clear the interrupt by writing a 1 to the corresponding bit of the GPIO_PORT_EOI_L/GPIO_PORT_EOI_H registers. This write operation also clears the interrupt status and raw status registers. Writing to the interrupt clear registers has no effect on level-sensitive interrupts. If level-sensitive interrupts cause the processor to interrupt, then the ISR can poll the interrupt raw status register until the interrupt source disappears, or it can write to the interrupt mask register to mask the interrupt before exiting the ISR. If the ISR exits without masking or disabling the interrupt prior to exiting, then the level-sensitive interrupt repeatedly requests an interrupt until the interrupt is cleared at the source.

The interrupts are combined into an active-high interrupt output signal. In order to mask the combined interrupt, all individual interrupts have to be masked. The single combined interrupt does not have its own mask bit.

Whenever I/O port is configured for interrupts, the data direction must be set to Input. If the data direction is reprogrammed to Output, then any pending edge-sensitive interrupts are not lost. However, no new interrupts are generated, and level-sensitive interrupts are lost.

Interrupt signals are internally synchronized to a system clock pclk_intr, which is connected to the APB bus clock pclk. Therefore, the pclk needs to be running for interrupt detection.

17.3.3 Debounce Operation

The external signal can be debounced to remove any spurious glitches that are less than half period of the external debouncing clock.

When an input interrupt signal is debounced using a slow debounce clock (external input clock dbclk or internal divided clock dbclk_div), the signal must be active for a minimum of one cycle of the debounce clock to guarantee that it is registered. Any input pulse widths less than half debounce clock period are bounced. A pulse width between half and one debounce clock width may or may not propagate, depending on its phase relationship to the debounce clock. If the input pulse spans rising edges and falling edge of the debounce clock, it is registered. If it spans only one edge, it is not registered.

The debounce function can be controlled by programming the debounce enable registers (GPIO_DEBOUNCE_L/GPIO_DEBOUNCE_H), debounce clock divide enable registers (GPIO_DBCLK_DIV_EN_L/GPIO_DBCLK_DIV_EN_H) and debounce clock divide control register (GPIO_DBCLK_DIV_CON).

17.3.4 Four OS Operation and Four Interrupts

To select this mode, virtual enable register should be set (GPIO_VIRTUAL_EN). Then all the configures can be allotted to four OS (for example OS_A, OS_B, OS_C, OS_D). OS_A will use the original address offset, OS_B will use the offset + 0x1000, OS_C will use the offset + 0x2000, OS_D will use the offset + 0x3000. The 32 bit I/O port should also be allotted to

Rockchip Confidential

the OS by setting reg group registers (GPIO_REG_GROUP_L and GPIO_REG_GROUP_H). Once reg group is set, the I/O operation can only be used by the setting address offset. Each OS has its own interrupt for I/O port, this is depended on reg group.
If virtual enable register is disable, reg group can also be used to allotted I/O interrupt. These four independent interrupts may be used for priority interrupt setting.

17.3.5 Burr filtration

The input signal from the PAD is filtered by filter to remove burrs and then sent to GPIO IP. The filter module can be selected to turn on or off, and the width of the filter burr can be configured. GPIO0-4 is connected to the filter in the table，the table lists the location of the register controlling filter in the GRF. See Chapter GRF for a more detailed description:

Table 17-1 GPIO filter Description

Module	Filter Name	Filter Info
GPIO0	GPIO0_FILTER	PMUGRF_SOC_CON5 [3:0]=gpio0_filter_en PMUGRF_SOC_CON5 [8:4]=gpio0_filter_sel0 PMUGRF_SOC_CON5 [14:10]=gpio0_filter_sel1 PMUGRF_SOC_CON6 [8:4]=gpio0_filter_sel2 PMUGRF_SOC_CON6 [14:10]=gpio0_filter_sel3 PMUGRF_SOC_CON7 [19:0]=gpio0_filter_count0 PMUGRF_SOC_CON8 [19:0]=gpio0_filter_count1 PMUGRF_SOC_CON9 [19:0]=gpio0_filter_count2 PMUGRF_SOC_CON10 [19:0]=gpio0_filter_count3
GPIO1_SHADOW	GPIO1_SHADOW_FILTER	PMUGRF_SOC_CON11 [3:0]=gpio1_shadow_filter_en PMUGRF_SOC_CON11 [8:4]=gpio1_shadow_filter_sel0 PMUGRF_SOC_CON11 [14:10]=gpio1_shadow_filter_sel1 PMUGRF_SOC_CON12 [8:4]=gpio1_shadow_filter_sel2 PMUGRF_SOC_CON12 [14:10]=gpio1_shadow_filter_sel3 PMUGRF_SOC_CON13 [19:0]=gpio1_shadow_filter_count0 PMUGRF_SOC_CON14 [19:0]=gpio1_shadow_filter_count1 PMUGRF_SOC_CON15 [19:0]=gpio1_shadow_filter_count2 PMUGRF_SOC_CON16 [19:0]=gpio1_shadow_filter_count3
GPIO1	GPIO1_FILTER	COREGRF_SOC_CON0 [3:0]=gpio1_filter_en COREGRF_SOC_CON0 [8:4]=gpio1_filter_sel0 COREGRF_SOC_CON0 [14:10]=gpio1_filter_sel1 COREGRF_SOC_CON1 [8:4]=gpio1_filter_sel2 COREGRF_SOC_CON1 [14:10]=gpio1_filter_sel3 COREGRF_SOC_CON2 [19:0]=gpio1_filter_count0 COREGRF_SOC_CON3 [19:0]=gpio1_filter_count1 COREGRF_SOC_CON4 [19:0]=gpio1_filter_count2 COREGRF_SOC_CON5 [19:0]=gpio1_filter_count3
GPIO2/GPIO3/GPIO4	GPIO2_FILTER	GRF_SOC_CON31 [3:0]=gpio2_filter_en GRF_SOC_CON31 [9:4]=gpio2_filter_sel0 GRF_SOC_CON31 [15:10]=gpio2_filter_sel1 GRF_SOC_CON32 [19:0]=gpio2_filter_count0 GRF_SOC_CON33 [19:0]=gpio2_filter_count1

GPIOX_FILTER Filters a maximum of four input burrs. Select "gpiox_filter_en" to enable four inputs. "gpiox_filter_selY" controls which pin of gpio corresponds to the Y input; "gpiox_filter_count" controls the width of the filter burrs. GPIO2_FILTER is shared by GPIO2/3/4.

Rockchip Confidential

17.3.6 Shadow GPIO

GPIO1 is in PD_CORE, it has a shadow GPIO1 is in PD_PMU. You can select whether IO is controlled by GPIO1 or GPIO1_SHADOW with PMUGRF_SOC_CON17/18.

17.4 Register Description

17.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
GPIO0	0xFF940000
GPIO1	0xFF870000
GPIO1_SHADOW	0xFF948000
GPIO2	0xFF1C0000
GPIO3	0xFF1D0000
GPIO4	0xFF1E0000

17.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
GPIO_SWPORT_DR_L	0x0000	W	0x00000000	Port Data Register (Low)

17.4.3 Detail Registers Description

GPIO_SWPORT_DR_L

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	swport_dr_low Output data for the lower 16 bits of I/O Port, each bit is individual. 1'b0: Low 1'b1: High Values written to this register are output on the I/O signals for the lower 16 bits of I/O Port if the corresponding data direction bits for I/O Port are set to Output mode. The value read back is equal to the last value written to this register.

GPIO_SWPORT_DR_H

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	swport_dr_high Output data for the upper 16 bits of I/O Port, each bit is individual. 1'b0: Low 1'b1: High Values written to this register are output on the I/O signals for the upper 16 bits of I/O Port if the corresponding data direction bits for I/O Port are set to Output mode. The value read back is equal to the last value written to this register.

GPIO_SWPORT_DDR_L

Address: **Operational Base** + offset (0x0008)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	swport_ddr_low Data direction for the lower 16 bits of I/O Port, each bit is individual. 1'b0: Input 1'b1: Output Values written to this register independently control the direction of the corresponding data bit in the lower 16 bits of I/O Port.

GPIO_SWPORT_DDR_H

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	swport_ddr_high Data direction for the upper 16 bits of I/O Port, each bit is individual. 1'b0: Input 1'b1: Output Values written to this register independently control the direction of the corresponding data bit in the upper 16 bits of I/O Port.

GPIO_INT_EN_L

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_en_low Allows each bit of the lower 16 bits of I/O Port to be configured for interrupts. 1'b0: Interrupt is disabled 1'b1: Interrupt is enabled Whenever a 1 is written to a bit of this register, it configures the corresponding bit on I/O Port to become an interrupt source; otherwise, I/O Port operates as a normal GPIO signal. Interrupts are disabled on the corresponding bits of I/O Port if the corresponding data direction register is set to Output.

GPIO_INT_EN_H

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	int_en_high Allows each bit of the upper 16 bits of I/O Port to be configured for interrupts. 1'b0: Interrupt is disabled 1'b1: Interrupt is enabled Whenever a 1 is written to a bit of this register, it configures the corresponding bit on I/O Port to become an interrupt source; otherwise, I/O Port operates as a normal GPIO signal. Interrupts are disabled on the corresponding bits of I/O Port if the corresponding data direction register is set to Output.

GPIO_INT_MASK_L

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_mask_low Controls whether an interrupt on the lower 16 bits of I/O Port can create an interrupt for the interrupt controller by not masking it. 1'b0: Interrupt is unmasked 1'b1: Interrupt is masked Whenever a 1 is written to a bit in this register, it masks the interrupt generation capability for this signal; otherwise interrupts are allowed through.

GPIO_INT_MASK_H

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_mask_high Controls whether an interrupt on the upper 16 bits of I/O Port can create an interrupt for the interrupt controller by not masking it. 1'b0: Interrupt is unmasked 1'b1: Interrupt is masked Whenever a 1 is written to a bit in this register, it masks the interrupt generation capability for this signal; otherwise interrupts are allowed through.

GPIO_INT_TYPE_L

Address: **Operational Base** + offset (0x0020)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	int_type_low Controls the type of interrupt that can occur on the lower 16 bits of I/O Port. 1'b0: Level-sensitive 1'b1: Edge-sensitive Whenever a 1 is written to a bit of this register, it configures the interrupt type to be edge-sensitive; otherwise, it is level-sensitive.

GPIO_INT_TYPE_H

Address: **Operational Base** + offset (0x0024)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_type_high Controls the type of interrupt that can occur on the upper 16 bits of I/O Port. 1'b0: Level-sensitive 1'b1: Edge-sensitive Whenever a 1 is written to a bit of this register, it configures the interrupt type to be edge-sensitive; otherwise, it is level-sensitive.

GPIO_INT_POLARITY_L

Address: **Operational Base** + offset (0x0028)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_polarity_low Controls the polarity of edge or level sensitivity that can occur on the lower 16 bits of I/O Port. 1'b0: Active-low 1'b1: Active-high Whenever a 1 is written to a bit of this register, it configures the interrupt type to rising-edge or active-high sensitive; otherwise, it is falling-edge or active-low sensitive.

GPIO_INT_POLARITY_H

Address: **Operational Base** + offset (0x002C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_polarity_high Controls the polarity of edge or level sensitivity that can occur on the upper 16 bits of I/O Port. 1'b0: Active-low 1'b1: Active-high Whenever a 1 is written to a bit of this register, it configures the interrupt type to rising-edge or active-high sensitive; otherwise, it is falling-edge or active-low sensitive.

Rockchip Confidential

GPIO_INT_BOTHEDGE_L

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_bothedge_low Controls the edge type of interrupt that can occur on the lower 16 bits of I/O Port. 1'b0: Disable both-edge detection 1'b1: Enable both-edge detection Whenever a particular bit is programmed to 1, it enables the generation of interrupts on both the rising edge and the falling edge of an external input signal corresponding to that bit on I/O Port. The values programmed in the registers int_type_low and int_polarity_low for this particular bit are not considered when the corresponding bit of this register is set to 1. Whenever a particular bit is programmed to 0, the interrupt type depends on the value of the corresponding bits in the int_type_low and int_polarity_low registers.

GPIO_INT_BOTHEDGE_H

Address: **Operational Base** + offset (0x0034)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	int_bothedge_high Controls the edge type of interrupt that can occur on the upper 16 bits of I/O Port. 1'b0: Disable both-edge detection 1'b1: Enable both-edge detection Whenever a particular bit is programmed to 1, it enables the generation of interrupts on both the rising edge and the falling edge of an external input signal corresponding to that bit on I/O Port. The values programmed in the registers int_type_high and int_polarity_high for this particular bit are not considered when the corresponding bit of this register is set to 1. Whenever a particular bit is programmed to 0, the interrupt type depends on the value of the corresponding bits in the int_type_high and int_polarity_high registers.

GPIO_DEBOUNCE_L

Address: **Operational Base** + offset (0x0038)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	debounce_low Controls whether an external signal of the lower 16 bits of I/O Port that is the source of an interrupt needs to be debounced to remove any spurious glitches. 1'b0: Disable debounce 1'b1: Enable debounce Writing a 1 to a bit in this register enables the debouncing circuitry. A signal must be valid for two periods of an external clock before it is internally processed.

GPIO_DEBOUNCE_H

Address: **Operational Base** + offset (0x003C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	debounce_high Controls whether an external signal of the lower 16 bits of I/O Port that is the source of an interrupt needs to be debounced to remove any spurious glitches. 1'b0: Disable debounce 1'b1: Enable debounce Writing a 1 to a bit in this register enables the debouncing circuitry. A signal must be valid for two periods of an external clock before it is internally processed.

GPIO_DBCLK_DIV_EN_L

Address: **Operational Base** + offset (0x0040)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	dbclk_div_en_low Controls whether to use the internal divided clock when debounce function is enabled for an external signal of the lower 16 bits of I/O Port. 1'b0: Disable divider for debounce clock 1'b1: Enable divider for debounce clock Whenever a 1 is written to a bit of this register, the clock divided from dbclk is used as debounce clock; otherwise, the original dbclk is used. The clock divide factor depends on the register dbclk_div_con. The values programmed in this register for this particular bit are not considered when the corresponding bit of the register debounce_low is set to 0.

GPIO_DBCLK_DIV_EN_H

Address: **Operational Base** + offset (0x0044)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

Rockchip Confidencial

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	dbclk_div_en_high Controls whether to use the internal divided clock when debounce function is enabled for an external signal of the upper 16 bits of I/O Port. 1'b0: Disable divider for debounce clock 1'b1: Enable divider for debounce clock Whenever a 1 is written to a bit of this register, the clock divided from dbclk is used as debounce clock; otherwise, the original dbclk is used. The clock divide factor depends on the register dbclk_div_con. The values programmed in this register for this particular bit are not considered when the corresponding bit of the register debounce_high is set to 0.

GPIO_DBCLK_DIV_CON

Address: **Operational Base** + offset (0x0048)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:0	RW	0x000001	dbclk_div_con dbclk_div = dbclk / (dbclk_div_con + 1)

GPIO_INT_STATUS

Address: **Operational Base** + offset (0x0050)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	int_status Interrupt status of I/O Port.

GPIO_INT_RAWSTATUS

Address: **Operational Base** + offset (0x0058)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	int_rawstatus Interrupt raw status of I/O Port (premasking bits).

GPIO_PORT_EOI_L

Address: **Operational Base** + offset (0x0060)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	R/W SC	0x0000	port_eoi_low Controls the clearing of edge type interrupts from the lower 16 bits of I/O Port. 1'b0: Nothing 1'b1: Clear edge-sensitive interrupt When a 1 is written into a corresponding bit of this register, the interrupt is cleared and the bit is self cleared at once. Writing to this register has no effect on level-sensitive interrupts. All interrupts are cleared when I/O Port is not configured for interrupts.

GPIO_PORT_EOI_H

Address: **Operational Base** + offset (0x0064)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	R/WSC	0x0000	port_eoi_high Controls the clearing of edge type interrupts from the upper 16 bits of I/O Port. 1'b0: Nothing 1'b1: Clear edge-sensitive interrupt When a 1 is written into a corresponding bit of this register, the interrupt is cleared and the bit is self cleared at once. Writing to this register has no effect on level-sensitive interrupts. All interrupts are cleared when I/O Port is not configured for interrupts.

GPIO_EXT_PORT

Address: **Operational Base** + offset (0x0070)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	ext_port This register always reflects the value of the signals on the external I/O Port.

GPIO_VER_ID

Address: **Operational Base** + offset (0x0078)

Bit	Attr	Reset Value	Description
31:0	RO	0x010219c8	ver_id Version ID.

GPIO_STORE_ST_L

Address: **Operational Base** + offset (0x0080)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	store_st_l This reigister can store the state for each GPIO by user writting to this register.

GPIO_STORE_ST_H

Address: **Operational Base** + offset (0x0084)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	store_st_h This reigister can store the state for each GPIO by user writting to this register.

GPIO_GPIO_REG_GROUP_L

Address: **Operational Base** + offset (0x0100)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	gpio_reg_group_low This register control the low 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP0 with offset 0x0000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag0 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_REG_GROUP_H

Address: **Operational Base** + offset (0x0104)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0xffff	gpio_reg_group_high This register control the high 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP0 with offset 0x0000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag0 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_VIRTUAL_EN

Address: **Operational Base** + offset (0x0108)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:1	RO	0x0000	reserved
0	RW	0x0	gpio_virtual_en 1'b1: Enable virtual, two OS supported 1'b0: Disable virtual. Only in GROUP0 with offset 0x0000.

GPIO_GPIO_REG_GROUP1_L

Address: **Operational Base** + offset (0x0110)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

Rockchip Confidencial

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	gpio_reg_group1_low This register control the low 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP1 with offset 0x1000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag1 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_REG_GROUP1_H

Address: **Operational Base** + offset (0x0114)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	gpio_reg_group1_high This register control the high 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP1 with offset 0x1000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag1 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_REG_GROUP2_L

Address: **Operational Base** + offset (0x0118)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	gpio_reg_group2_low This register control the low 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP2 with offset 0x2000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag2 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_REG_GROUP2_H

Address: **Operational Base** + offset (0x011C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	gpio_reg_group2_high This register control the high 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP2 with offset 0x2000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag2 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_REG_GROUP3_L

Address: **Operational Base** + offset (0x0120)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	gpio_reg_group3_low This register control the low 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP3 with offset 0x3000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag3 1'b0: GPIO interrupt connect to other interrupt

GPIO_GPIO_REG_GROUP3_H

Address: **Operational Base** + offset (0x0124)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_mask Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	gpio_reg_group3_high This register control the high 16 bit of GPIO and each bit corresponds each GPIO. When virtual_en=1'b1: 1'b1: GPIO control by GROUP3 with offset 0x3000 1'b0: GPIO control by other GROUP. When virtual_en=1'b0: 1'b1: GPIO interrupt connect to gpio_int_flag3 1'b0: GPIO interrupt connect to other interrupt

Notes: Unused Module Pin is tied to zero!
Notes: I=input, O=output, I/O=input/output, bidirectional

17.6 Application Notes

- Reading from an unused location or unused bits in a particular register always returns zeros. There is no error mechanism in the APB.
- Programming the GPIO registers for interrupt detection should be completed prior to enabling the interrupts in order to prevent spurious glitches on the interrupt output signal to the interrupt controller.

17.6.1 GPIO Mode of SARADC

The pad of GPIO4_B0/GPIO4_B1/GPIO4_B2/GPIO4_B3 are shared with SARADC and can be used as 1.8V input/output. Before using GPIO4_B0~ GPIO4_B3 as common GPIO, you must send 0x00F000F0 to register 0xFF4D8840 (GPIO4_IOC_SARADC_CON) first to set GPIO intput enable. And you can configure other GPIO properties in GPIO4_IOC_SARADC_CON (e.g. pull up/down, Schmitter).

17.6.2 GPIO Mode of SARADC

The pad of GPIO4_A0/GPIO4_A1/GPIO4_A2/GPIO4_A3/GPIO4_A4/ GPIO4_A5 are shared with MIPI D-PHY and can be used as 1.8V output. To switch mode to GPIO, refer to the MIPI D-PHY Chapter.

17.6.3 Configuration of GPIO0D0

GPIO0D0 is configured using a separate register GPIO0_IOC_GPIO0D_CON (address 0xFF950830). Select the function by the following values:

- GPIO0_IOC_GPIO0D_CON [1:0]==2 'b00 for GPIO mode
- GPIO0_IOC_GPIO0D_CON [1:0]==2' b01 for OSC_CLK_OUT
- GPIO0_IOC_GPIO0D_CON [1:0]==2 'b10 for REF_CLK0_OUT

Rockchip Confidential

Chapter 18 IO Controller (IOC)

18.1 Overview

The IO Controller (IOC) will be used by the software to do some static Settings related to IOs.

18.2 Function Description

The functions of the IO Controller (IOC) are as follows:

- GPIO IOMUX control
- GPIO PAD pull-up/pull-down, drive strength, power supply voltage and other configurations

18.3 GPIO0_IOC Register Description

18.3.1 Registers Summary

Name	Offset	Size	Reset Value	Description
GPIO0_IOC_GPIO0A_IOMUX_SEL_0	0x0000	W	0x00000000	GPIO0A IOMUX Select Register 0
GPIO0_IOC_GPIO0A_IOMUX_SEL_1	0x0004	W	0x00000000	GPIO0A IOMUX Select Register 1
GPIO0_IOC_GPIO0B_IOMUX_SEL_0	0x0008	W	0x00000000	GPIO0B IOMUX Select Register 0
GPIO0_IOC_GPIO0B_IOMUX_SEL_1	0x000C	W	0x00000000	GPIO0B IOMUX Select Register 1

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

18.5.2 Detail Registers Description

GPIO2_IOC_GPIO2A_IOMUX_SEL_0

Address: Operational Base(0xFF4D8000) + offset (0x0040)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:12	RW	0x0	gpio2a3_sel 4'h0: GPIO2_A3 4'h1: FSPI_D1
11:8	RW	0x0	gpio2a2_sel 4'h0: GPIO2_A2 4'h1: FSPI_D0
7:4	RW	0x0	gpio2a1_sel 4'h0: GPIO2_A1 4'h1: FSPI_CLK
3:0	RW	0x0	gpio2a0_sel 4'h0: GPIO2_A0 4'h1: FSPI_CSN

GPIO2_IOC_GPIO2A_IOMUX_SEL_1

Address: Operational Base(0xFF4D8000) + offset (0x0044)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:8	RO	0x00	reserved
7:4	RW	0x0	gpio2a5_sel 4'h0: GPIO2_A5 4'h1: FSPI_D3
3:0	RW	0x0	gpio2a4_sel 4'h0: GPIO2_A4 4'h1: FSPI_D2

GPIO2_IOC_GPIO2B_IOMUX_SEL_0

Address: Operational Base(0xFF4D8000) + offset (0x0048)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:12	RW	0x0	gpio2b3_sel 4'h0: GPIO2_B3 4'h1: ETH_RMII0_TXD0 4'h2: SPI2_MISO
11:8	RW	0x0	gpio2b2_sel 4'h0: GPIO2_B2 4'h1: ETH_RMII0_CLK 4'h2: SPI2_MOSI
7:4	RW	0x0	gpio2b1_sel 4'h0: GPIO2_B1 4'h1: ETH_RMII0_RXD1 4'h2: SPI2_CSN

18.8 Application Notes

IOC is usually connected to a functional IP in the following ways (take input as an example):

1) As shown in following figure, the IO PAD connects directly to the function IP through IOC, and IOC_IOMUX_SEL (for example, GPIO0_IOC_GPIO0A_IOMUX_SEL_0) controls which IP the signal is input to.

Rockchip Confidencial

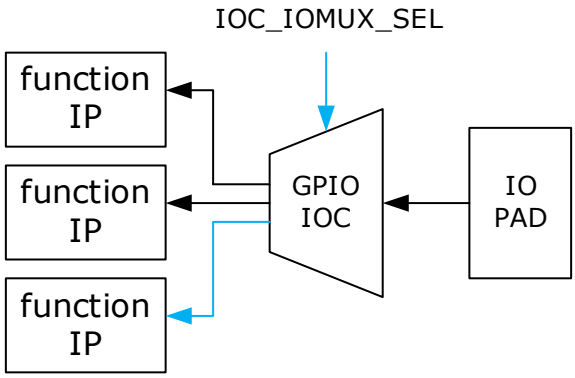

Fig. 18-1 Connect directly from IOC to function IP

2) As shown in following figure, some IP will be connected to the IO PAD via RMIO and IOC. In this case, you need to configure IOC_IOMUX_SEL to select RMIO (for example, GPIO0_IOC_GPIO0A_IOMUX_SEL_0=4 'h7) and then configure RMIO FUNC_SEL so that one of the IP in the orange box is selected to complete stroking with the IO PAD.

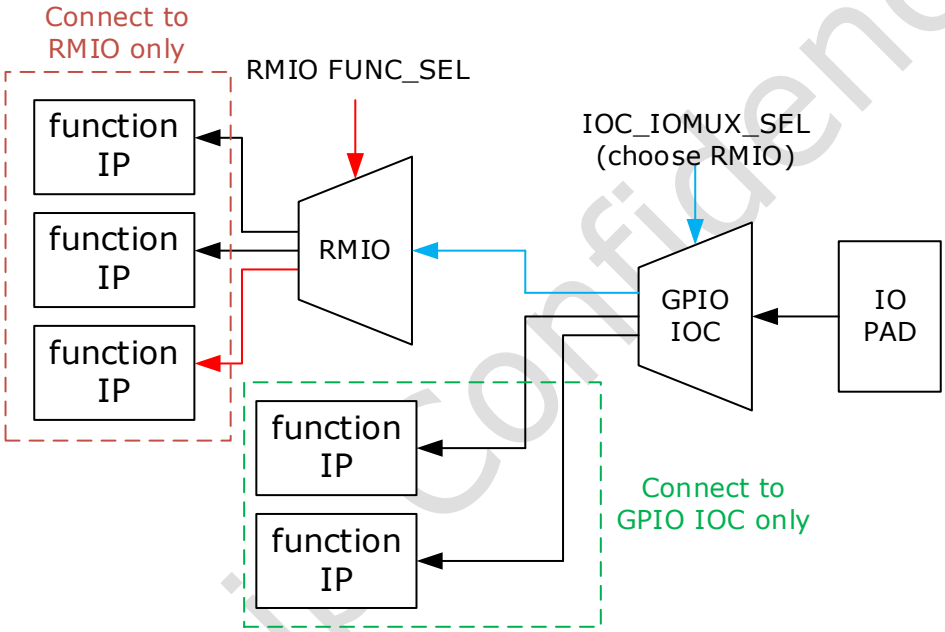

Fig. 18-2 Some IPs are connected to the IO PAD through RMIO and IOC

3) As shown in following figure, the IP can be connected to the IO PAD only through IOC, or through RMIO+IOC. In this case, you need to configure RMIO_FUNC_SEL, and IOC_IOMUX_SEL to select one of the paths. The IOC will have a higher priority.

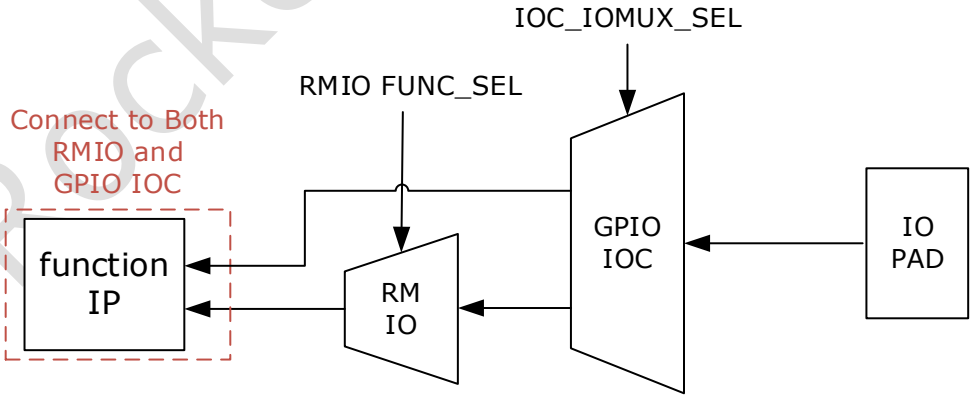

Fig. 18-3 IP which has multiple paths connecting to the I/O PAD

Chapter 19 Rockchip Matrix IO

19.1 Overview

The Rockchip Matrix IO (RM_IO) can be configured with registers to route arbitrary signals from low-speed IP, such as UART/I2C, to the selected IO PAD.
RM_IO has the following features:

- Supports routing any IP signal in the optional range to the IO PAD
- The IP signal that is not routed to the IO PAD is tied to the default value

19.2 Block Diagram

RM_IO is comprised of:

- Config Interface

This interface controls which IP pins Rockchip Matrix IO routes to RM_IOx.

- IP Interface

IP interfaces connect signals from peripheral IP, including input/output/output enablement.

- RM_IO0~RM_IOx

These signals are connected to IOMUX. When IOMUX's SEL signal is configured to a specific value, RM_IOx connects to the IO PAD. That is, RM_IO0 is connected to PAD0 through IOMUX, and RM_IO1 is connected to PAD1 through IOMUX.

- Test Interface

This interface controls the behavior in test mode.

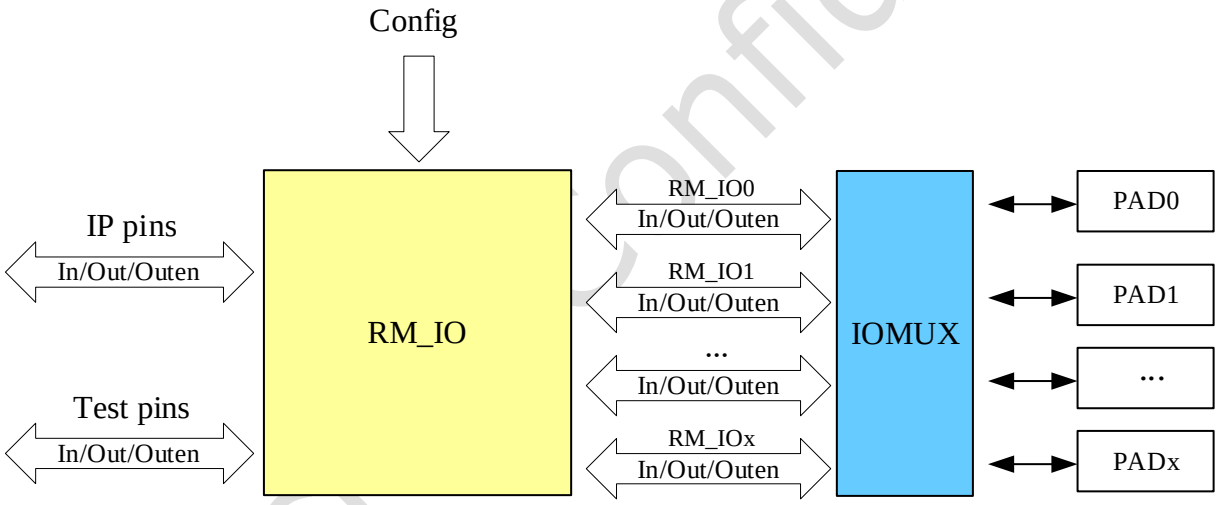

Fig. 19-1 RM_IO Block Diagram

19.3 Function Description

19.3.1 IP signal routing

The number of peripheral IP signals connected to RM_IO is greater than the number of pads. RM_IO can be configured by software to connect an IP signal to any PAD. The following is an example:

1) Write a value to RM_IO_rm_gpio0a0_sel by referring to the RM_IO register description in section 19.4 to configure the IP function pin of the RM_IO0 connection. The selected function pins can be viewed in 19.4.2 Detail Registers Description.
2) View the PAD name that RM_IO0 connects to by referring to Table 19-1. Set the value in IOMUX Setting to enable RM_IO0 to connect to the PAD through IOMUX.
3) You can perform steps 1 and 2 to configure any RM_IOx. Note that the function selection of multiple RM_IO cannot be the same; otherwise, conflicts will occur, causing the IP function pins to fail to connect to the PAD.

19.3.2 Test Mode

RM_IO can switch to the test mode through the register, which is used to find connection problems faster; after entering the Test mode, the value of the IP pins in Fig. 19-1 does not affect the input and output of RM_IO. Instead, the Test pins connect to the PAD through

Rockchip Confidential

RM_IO. To use it, follow the following steps:
1. Switch to test mode by setting GRF_PMU_SOC_CON1[11].
2. Repeat steps 1 and 2 in Section 1.3.1 to connect the Test pins to the PAD.
3. The value of Test pins (output/output enable driven to RM_IO) is controlled by registers PMUGRF_OS_REG0/1/2/3 (To control output0 ~97) and PMUGRF_OS_REG4/5/6/7(To control output enable0 ~ 97). The RM_IO_test_status register can be used to obtain the Test pins (the value driven to the Test pins by RM_IO) and the values of the RM_IO0~RM_IOx pins.

19.4 Register Description

19.4.1 Registers Summary

Name	Offset	Size	Reset Value	Description
RM_IO_rm_gpio0a0_sel	0x0080	W	0x00000000	Configure the rm_io0 function
RM_IO_rm_gpio0a1_sel	0x0084	W	0x00000000	Configure the rm_io1 function
RM_IO_rm_gpio0a2_sel	0x0088	W	0x00000000	Configure the rm_io2 function

Notes: I=input, O=output, I/O=input/output

19.6 Application Notes

- If multiple RM_IO configurations are configured for the same function (for example, RM_GPIO0A0_SEL == RM_GPIO0A1_SEL), a conflict will occur. The input and output of both RM_IO are fixed to their default values.

Rockchip Confidential

Chapter 20 Audio Subsystem

20.1 Overview

The audio subsystem is dedicated for managing the audio resources of the whole chip. In RK3506, the audio subsystem consists of three pieces: BUS_WRAPPER, LS_PERI wrapper and HS_PERI wrapper. With the audio subsystem, we can combine audio components and the embedded SOC platform together and provide an audio system solution.

20.2 Block Diagram

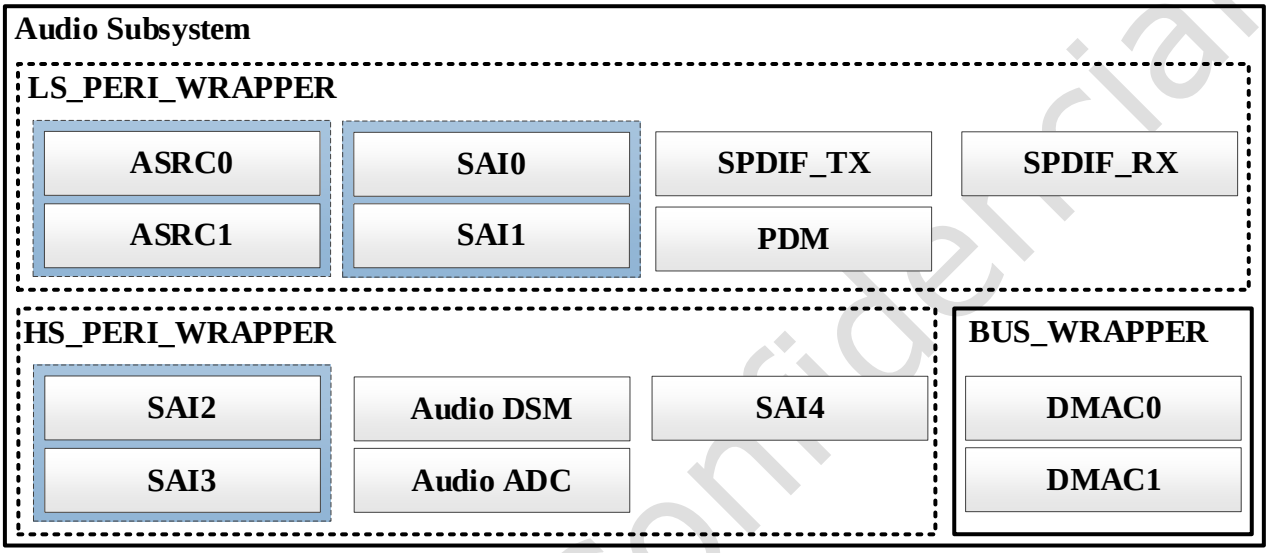

Fig. 20-1 Audio Subsystem Block Diagram

LS_PERI Wrapper

LS_PERI Wrapper consists of audio components shown as follow:

- One PDM
- One SPDIF_TX
- One SPDIF_RX
- SAI0 (1 tx, 4 rx lanes) and SAI1 (4 tx, 1 rx lanes), which can be combined together
- Two 4 channel ASRC0/1, which can be combined together. Audio components in the HS_PERI wrapper can also converted using ASRC0/1, not just the audio components in LS_PERI wrapper.

HS_PERI Wrapper

HS_PERI Wrapper consists of audio components shown as follow:

- One Audio ADC
- One Audio DSM, which can be used to play audio data from SAI3
- SAI2/3 (1 lane), which can be combined together
- SAI4 (1 rx lane), which can be used to receive data from Audio ADC

BUS Wrapper

BUS Wrapper consists of two multichannel DMA called DMAC0 and DMAC1, which can be used to transmit audio data.

20.3 Function Description

In this chapter, we will only cover the interconnection of these audio components. For the detail of audio components, please refer to the following chapters: Audio DSM, Audio ADC, SPDIF Transmitter, SPDIF Receiver, PDM, Serial Audio Interface (SAI) and Asynchronous Sample Rate Converter (ASRC).

20.3.1 SAI Series Mode

In series mode, SAIs in LS_PERI wrapper or HS_PERI wrapper can be combined together to

Rockchip Confidential

enhance throughput. We can appoint the SAI at the front as master and other SAIs as slave. In RK3506, SAI0 as master and SAI1 as slave when combined, SAI2 as master and SAI3 as slave when combined.
In series mode, the following internal signals interact to ensure that the combined SAIs stay synchronized. Meanwhile, the FS interface and SCLK interface of slave SAI are derived from master SAI instead. Besides, all combined SAIs can be viewed as a whole and interact with the outside world using their respective interface. We can take LS_PERI wrapper series mode as an example in the following figure.

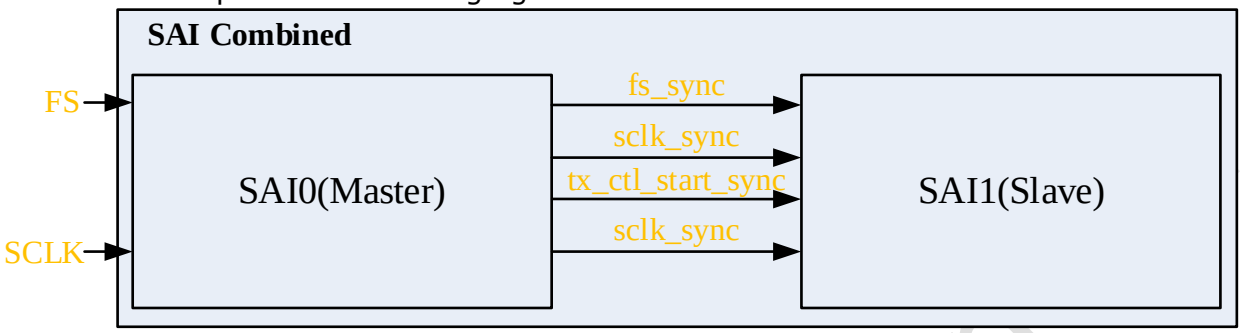

Fig. 20-2 SAI Series Mode Structure

20.3.2 ASRC Series Mode

In series mode, adjacent ASRCs in LS_PERI wrapper can be combined together to enhance throughput. We can appoint the ASRC at the front as master and other ASRCs as slave. In RK3506, ASRC0 as master and ASRC1 as slave when combined.
In series mode, all combined ASRCs can be viewed as a whole and interact with the outside world using the interface of master ASRC only. We can take MEM2MEM series mode in audio0 wrapper as an example in the following figure.

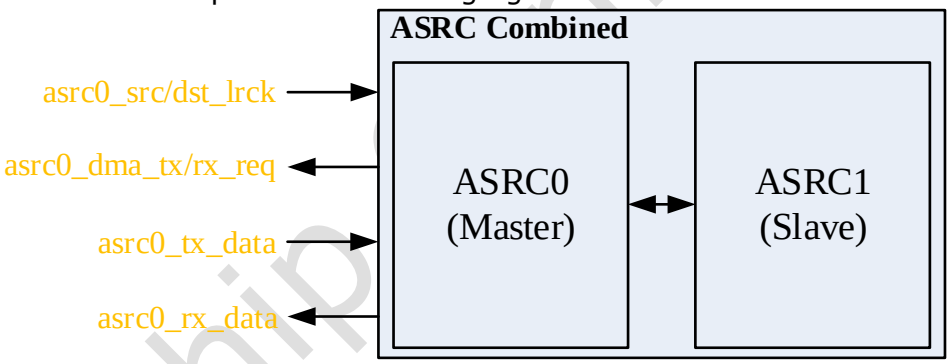

Fig. 20-3 ASRC MEM2MEM Series Mode Structure

In series mode of SAI and ASRC, only the clock source of master is used. Combined SAIs using their own DMA handshake interface and interrupt interface, but only the interface of master ASRC is used when combined.

20.3.3 SPDIF Mux

Usually, the output of SPDIF_TX is sent to IO. But for debug purpose, we can send the input of SPDIF_RX to IO instead using the following selector.

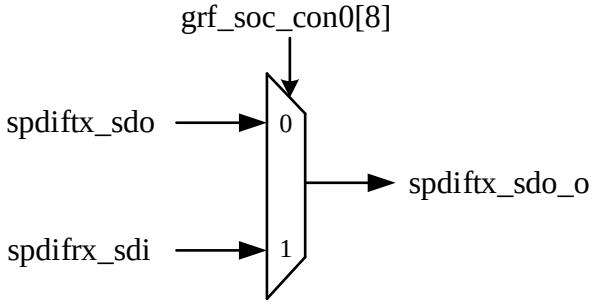

Fig. 20-4 SPDIF SDO Selector

20.3.4 Audio DSM and SAI3

Audio DSM can be used to play audio data from SAI3. Three possible application can be shown as follow.

- Audio DSM acts as slave and SAI3 as master

Rockchip Confidential

Clock source of audio DSM is from SAI3, and clock source of SAI3 is from CRU.

- Audio DSM acts as master and SAI3 as slave
  Clock source of audio DSM is from CRU, and clock source of SAI3 is from audio DSM.
- Both audio DSM and SAI3 acts as slave
  Clock source of audio DSM and SAI3 is from IO.

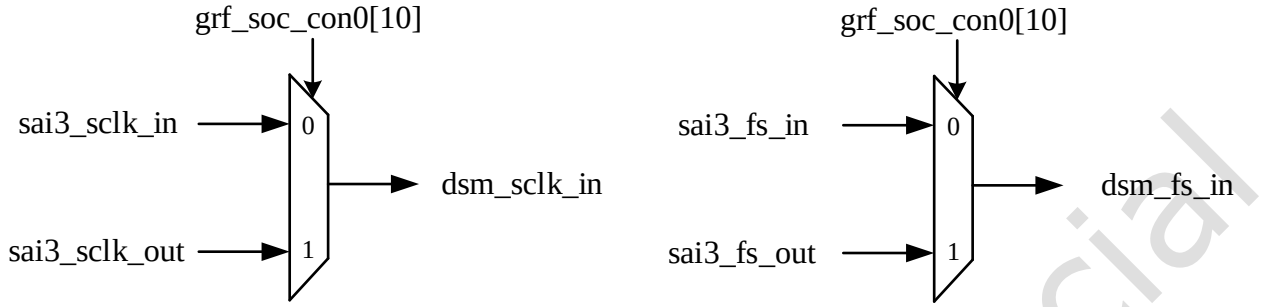

Fig. 20-5 Audio DSM Input Clock Selector

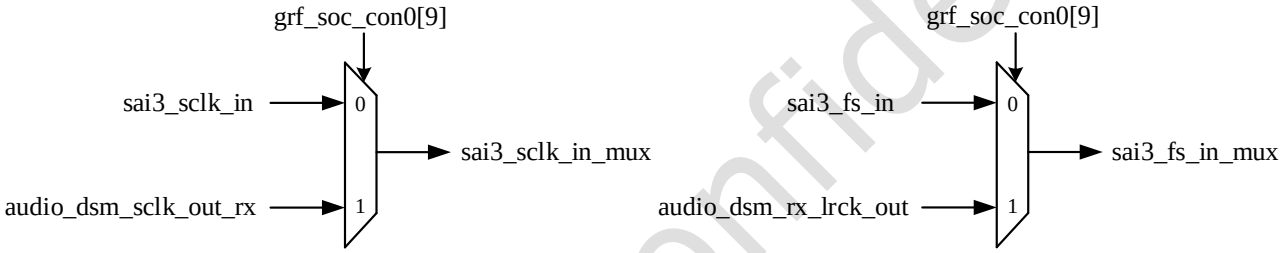

Fig. 20-6 SAI Input Clock Selector

Rockchip Confidencial

Chapter 21 Audio DSM

21.1 Overview

Audio DSM is a 16-bit digital audio encoder which supports multiple sample rates. It is mainly composed of digital DAC. The aim of digital DAC is to process the data received from I2S/PCM interface through filters, volume control and modulation.
The RK DSM supports the following features.

- Support 8-bit APB and AHB bus slave interface
- Support 2-channel digital DAC
- Support I2S/PCM interface
- Support I2S/PCM master and slave mode
- Support 2-channel audio receiving in I2S mode
- Support 2-channel audio receiving in PCM mode
- Support I2S normal, left and right justified mode serial audio data transfer
- Support PCM early, late1, late2, late3 mode serial audio data transfer
- Support MSB or LSB first serial audio data transfer
- Support configurable SCLK and LRCK polarity
- Support 16 bit sample resolution
- Support programmable left and right channel exchangeable in I2S mode and PCM mode
- Support three modes of mixing for every digital DAC channel
- Support volume control
- Support programmable negative and positive volume gain

21.2 Block Diagram

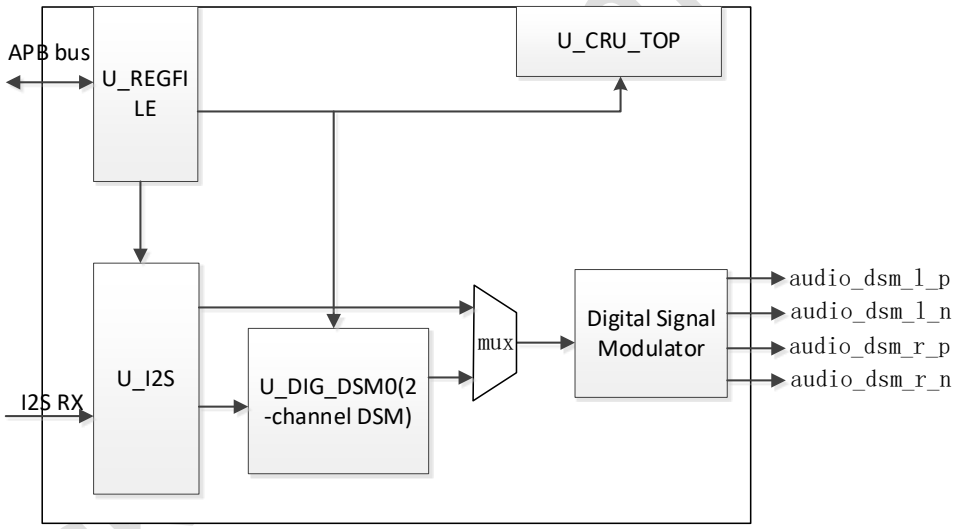

Fig.21-1 RK DSM Block Diagram

RK DSM_RF
The RK DSM_RF implements the 8-bit APB/AHB slave operation through APB/AHB bus. It is responsible for configuring the operation registers of other modules.
RK DSM_CRU
The RK DSM_CRU implements clock and reset generation function. It is responsible for generating sample clock, digital DAC operation clock and I2S operation clock.
RK DSM
There are 2 digital DAC channels. The digital DAC receives audio data from ACDC_I2S module. It includes one CIC filter, one high-pass filter, several low-pass decimation filters and other audio signal processing related modules. The output of digital DAC is sent to DSM modular before transmitting outside.
RK DSM_I2S
The I2S/PCM audio interface can be configured to master mode or slave mode. In Master Mode, SCLK and LRCK are configured as output. In slave mode, SCLK and LRCK are

Rockchip Confidential

configured as input. The RK DSM_I2S module can only operate in RX mode. When in RX mode, it receives audio data from I2S RX interface and sends it to digital DAC.

DSM Modulator

It is a modulator that converts 16 bits audio sample data to 1 bit audio data.

21.3 Function description

The I2S/PCM interface of Digital Audio Codec is connected to the I2S1 controller. Please refer to the I2S chapter for detailed information about I2S and PCM format that Digital Audio Codec supports.

21.3.1 Filters of Digital DAC

I2S module receives two-channel audio data from I2S RX interface and drives it to the digital DAC which supports mixing function or directly to the DSM modulator. How to pour 2-channel audio data into 2-channel digital DAC can be achieved by programming mixing mode.

The 2-channel digital DAC includes a high-pass filter and a maximum of 5 half-band filters. The high-pass filter is used to filter DC components in audio data stream. Result of high-pass filter is sent to the digital DAC volume control module. The input of 5 half-band filters comes from output of volume control module with each perform 2-times interpolation. But not all of them are working all the time. How many of them are needed to work depends on the sample rate of digital DAC. The result of half-band filters is sent to a modulator.

21.3.2 Volume Control

For digital DAC, output of high-pass filters is fed into volume control module. The volume control module inside digital DAC contains several sub-modules such as peak detect, frequency cross zero detect, LIMITER and digital gain control. It can be digitally attenuated over a range of -96dB~0dB in 0.375dB/step for negative gain and amplified over a range of 0dB~96dB in 0.375dB/step for positive gain. Whether is attenuated or amplified can be software programmed.

21.4 Register Description

21.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

21.4.2 Registers Summary

21.5 Interface Description

The I2S RX interface of Digital Audio Codec is connected to the TX interface of I2S1 when GRF_AUDIO_CON[14] is set to 1'b1.
When operating in audio DSM mode 0 or 1, Digital Audio Codec outputs two pairs of differential signals encoded in DSM format. The following table shows the RK DSM interface description for audio DSM mode.

Table 21-1 Audio DSM M0 Interface Description

Module Pin	Direction	Pad Name	IOMUX Setting
AUDIO_DSM_L_P	O	GPIO1_D1	GPIO1_IOC_GPIO1D_IOMUX_SEL_0[7:4]=4
AUDIO_DSM_L_N	O	GPIO1_D0	GPIO1_IOC_GPIO1D_IOMUX_SEL_0[3:0]=4
AUDIO_DSM_R_P	O	GPIO1_C2	GPIO1_IOC_GPIO1C_IOMUX_SEL_0[11:8]=4
AUDIO_DSM_R_N	O	GPIO1_C1	GPIO1_IOC_GPIO1C_IOMUX_SEL_0[7:4]=4

Table 21-2 Audio DSM M1 Interface Description

Module Pin	Direction	Pad Name	IOMUX Setting
AUDIO_DSM_L_P	O	GPIO2_B7	GPIO2_IOC_GPIO2B_IOMUX_SEL_1[15:12]=2
AUDIO_DSM_L_N	O	GPIO2_B6	GPIO2_IOC_GPIO2B_IOMUX_SEL_1[11:8]=2
AUDIO_DSM_R_P	O	GPIO2_B5	GPIO2_IOC_GPIO2B_IOMUX_SEL_1[7:4]=2
AUDIO_DSM_R_N	O	GPIO2_B4	GPIO2_IOC_GPIO2B_IOMUX_SEL_1[3:0]=2

21.6 Application Notes

21.6.1 Software Application Notes

Steps to configure Digital DAC to work in audio DSM mode 0 are as follows.
1. Program CRU in the SOC system to achieve the operation frequency of Digital DAC.
2. Program DSMINTMOD_DIV to 0x07.
3. Program DSMCLKCTRL to 0x3d.
4. Program DSMINTSCLK_DIV if Digital DAC I2S RX acts as master.
5. Program DSMDSM_CTRL to 0x58.
6. Program DSM_I2S_CKR0 and ACDCDIG_I2S_CKR1 to set I2S RX related registers.
7. Program DSM_I2S_CLR to clear RX logic.
8. Program DSM_I2S_RXCR0 and ACDCDIG_I2S_RXCR1.
9. Program GRF_AUDIO_CON[14] to 1'b1 and program registers of I2S1 that is connected to Digital Audio Codec. Don't start transfer at this time.
10. Program DAC related registers such as DSMHPF, DSMVUCTL and DSMCFG1 to achieve basic configuration.
11. Program ACDCDIG_I2S_XFER to start I2S RX.
12. Program registers of I2S1 outside Digital Audio Codec to start TX.
13. Program DSMDIGEN to enable digital DAC channels. From now on, the Digital Audio Codec begins to work.

Steps to configure Digital Audio Codec to end audio DSM mode 0 transfer are as follows.
1. Program registers of I2S1 to stop TX and ACDCDIG_I2S_XFER to stop RX.
2. Program DSMDSM_CTRL to 0x0.
3. Program DSMDIGEN to disable digital DAC channels.
4. Program DSMCLKCTRL to 0x0. Wait DSMCLKCTRL.dac_sync_status until read back to be 1'b0.

Steps to configure Digital DAC to work in audio DSM mode 1 are as follows.
1. Program CRU in the SOC system to achieve the operation frequency of Digital DAC.

Rockchip Confidential

2. Program DSMCLKCTRL to 0x3d.
3. Program DSMSCLKRXINT_DIV if Digital DAC I2S RX acts as master.
4. Program DSMDSM_CTRL to 0x68.
5. Program DSM_I2S_CKR0 and ACDCDIG_I2S_CKR1 to set I2S RX related registers.
6. Program DSM_I2S_CLR to clear RX logic.
7. Program DSM_I2S_RXCR0 and ACDCDIG_I2S_RXCR1.
8. Program GRF_AUDIO_CON[14] to 1'b1 and program registers of I2S1 to start TX.
9. Program DSM_I2S_XFER to start I2S RX. From now on, the Digital Audio Codec begins to work.

Steps to configure Digital Audio Codec to end audio DSM mode 1 transfer are as follows.

1. Program registers of I2S1 to stop TX and DSM_I2S_XFER to stop RX.
2. Program DSMDSM_CTRL to 0x0.
3. Program DSMCLKCTRL to 0x0. Wait DSMCLKCTRL.dac_sync_status until read back to be 1'b0.

Chapter 22 Audio ADC

22.1 Overview

Audio ADC is a 24-bit digital audio decoder which supports multiple sample rates. The function of Audio ADC is to convert external MIC input analog signal to I2S/PCM format audio data through a series of filters and volume control. The coding process of Audio ADC is controlled by the register through the APB Bus.
Audio ADC supports the following features.

- Support APB bus slave interface
- Support Analog gain between 0~48dB with 3db/step
- Support 1-channel Differential-mode/Single-mode/Pseudo-differential mode ADC
- Support I2S/PCM master and slave mode
- Support I2S normal, left and right justified mode serial audio data transfer
- Support PCM early, late1, late2, late3 mode serial audio data transfer
- Support MSB or LSB first serial audio data transfer
- Support 16 ~32bit sample resolution
- Support sample rate: 8kHz, 16kHz, 32kHz, 64kHz, 128kHz, 11.025kHz, 22.05kHz, 44.1kHz, 88.2kHz, 176.4kHz, 12kHz, 24kHz, 48kHz, 96kHz, 192kHz
- The passband of filters is 0.45625*fs
- Support passband ripple within +/-0.1dB
- The stopband of filters is 0.5*fs
- Support stopband attenuation at least 60dB
- Support Digital Audio ADC volume control
- Support programmable negative volume gain and positive volume gain.

22.2 Block Diagram

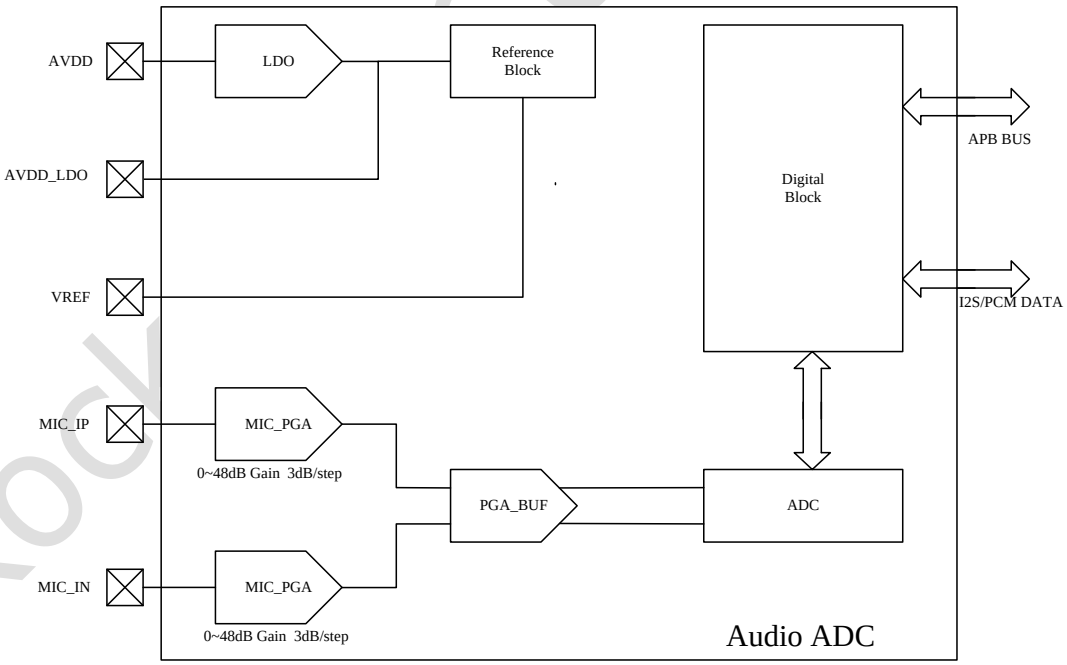

Fig. 22-1 Audio ADC Block Diagram

Rockchip Confidencial

22.3 Function Description

22.3.1 I2S normal mode

This is the waveform of I2S normal mode. For LRCK (i2s_lrck_tx) signal, it goes low to indicate left channel and high to right channel. For SD (i2s_sdo) signal, it starts sending the first bit (MSB or LSB) one SCLK clock cycle after LRCK changes. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

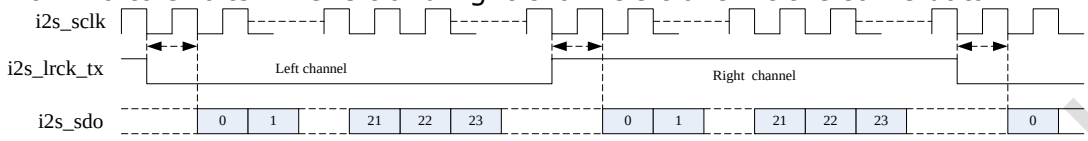

Fig.22-2 I2S Normal Mode Timing Format

22.3.2 I2S left justified mode

This is the waveform of I2S left justified mode. For LRCK (i2s_lrck_tx) signal, it goes high to indicate left channel and low to right channel. For SD (i2s_sdo) signal, it starts sending the first bit (MSB or LSB) at the same time when LRCK changes. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

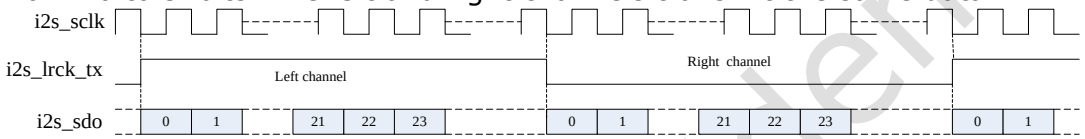

Fig.22-3 I2S Left Justified Mode Timing Format

22.3.3 I2S right justified mode

This is the waveform of I2S right justified mode. For LRCK (i2s_lrck_tx) signal, it goes high to indicate left channel and low to right channel. For SD (i2s_sdo) signal, it transfers MSB or LSB first; but what is different from I2S normal or left justified mode, the last bit of the transferred data is aligned to the transition edge of the LRCK signal while one bit is transferred at one SCLK cycle. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

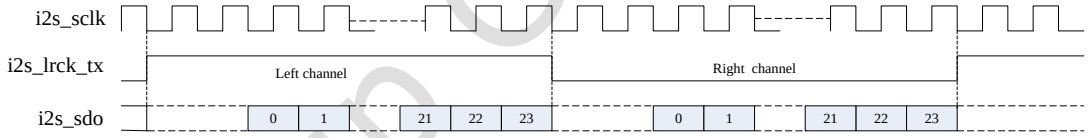

Fig.22-4 I2S Right Justified Mode Timing Format

22.3.4 PCM early mode

This is the waveform of PCM early mode. For LRCK (i2s_lrck_tx) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo) signal, it sends the first bit (MSB or LSB) at the same time when LRCK goes high. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

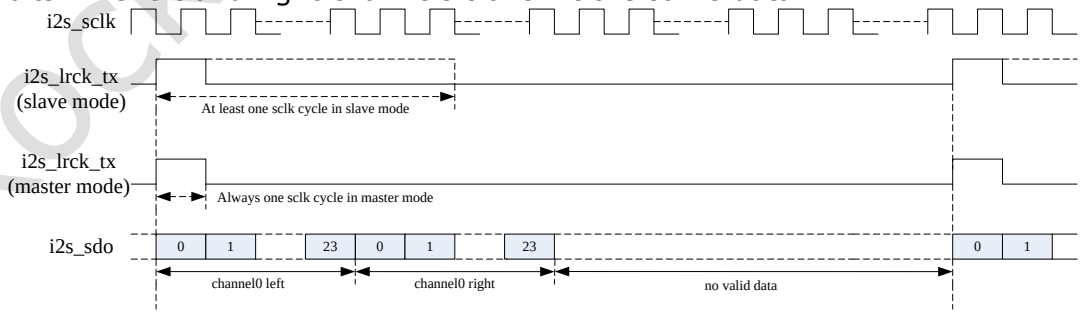

Fig.22-5 PCM Early Mode Timing Format

22.3.5 PCM late1 mode

This is the waveform of PCM late1 mode. For LRCK (i2s_lrck_tx) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo) signal, it sends the first bit (MSB or LSB) one SCLK clock cycle after LRCK goes high. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

Rockchip Confidential

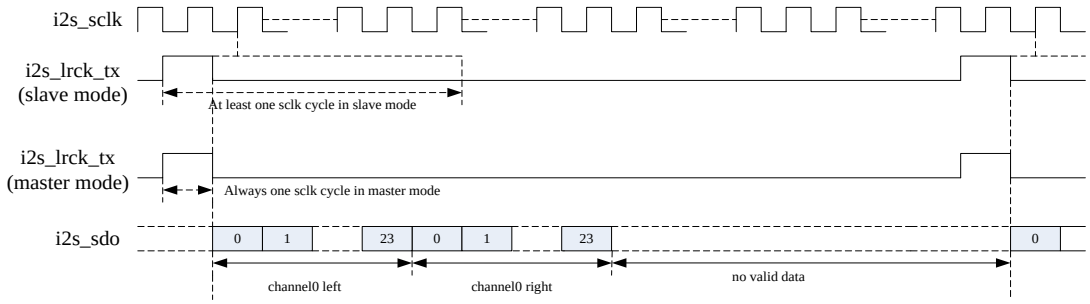

Fig.22-6 PCM Late1 Mode Timing Format

22.3.6 PCM late2 mode

This is the waveform of PCM late2 mode. For LRCK (i2s_lrck_tx) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo) signal, it sends the first bit (MSB or LSB) two SCLK clock cycles after LRCK goes high. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

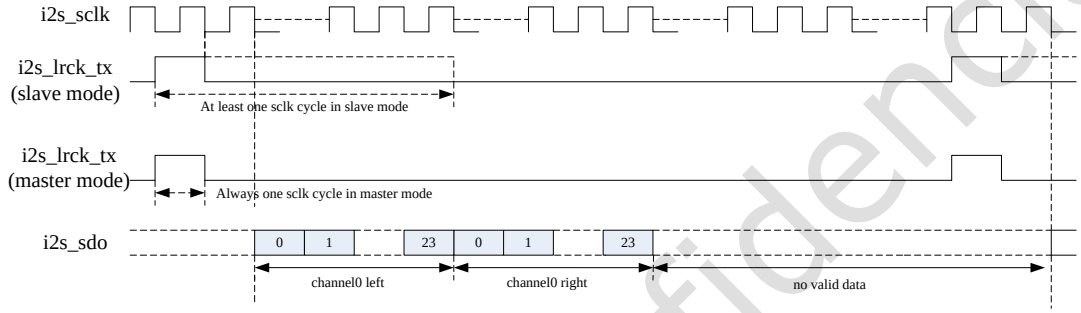

Fig.22-7 PCM Late2 Mode Timing Format

22.3.7 PCM late3 mode

This is the waveform of PCM late3 mode. For LRCK (i2s_lrck_tx) signal, it goes high to indicate the start of a group of audio channels. For SD (i2s_sdo) signal, it sends the first bit (MSB or LSB) three SCLK clock cycles after LRCK goes high. The range of SD signal width is from 16 to 32bits. The left and right channels transmit the same data.

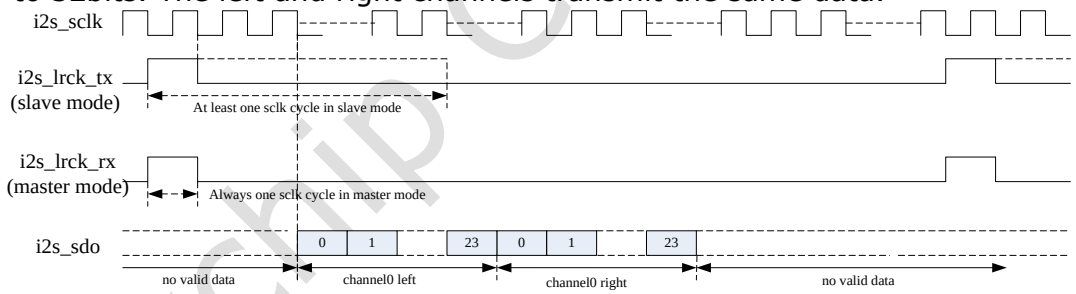

Fig.22-8 PCM Late3 Mode Timing Format

22.3.8 Digital Filters

In order to achieve PCM format audio data from input 1-bit data stream, a total of 5 filters are embedded in ADC module. It includes a CIC decimation filter, a compensation filter, 2 half-band filters and a high pass filter.

The CIC decimation filter achieves 8-timse or 16-times or 32-times or 64-times or 128-times decimation. Which decimation rate is selected depends on the sample rate. For example, in order to output a 12K sample rate signal, 128-times decimation rate need to be selected.

Compensation filter is connected in series following CIC filter. Its function is to reduce the ripple of CIC filter output. It can be software enabled or disabled. It is valid only when CIC decimation filter works in 32-times or 64-times decimation.

The 2 half-band filters each perform 2-times decimation.

The high pass filter is used to filter DC components in audio data stream. The result of high pass filter is sent to the volume control.

22.3.9 Volume Control

The PCM format data output from the high pass filter are fed into the volume control. It can be digitally attenuated over a range of -95.625dB~0dB in 0.375dB/step for negative gain.

Rockchip Confidential

The ADC IP has an 8-bit register for volume control. For negative gain, 0xff corresponds to digital mute while 0x00 corresponds to 0dB.

22.3.10 Frequency Configuration

ACDC_CLK is the input clock of Audio ADC. All internal clocks are generated by ACDC_CLK if the I2S module acts as a master. ACDC_CLK must be homologous to the operation clock of I2S master when the I2S module of Audio ADC acts as a slave. There is another clock named ADC_CLK acting as sample clock generated from ACDC_CLK and sent out to the Analogy Audio ADC. The relationship of ACDC_CLK, ADC_CLK and sample rates is as follows where the ACDC_CLK is 8 times of ADC_CLK. Make sure that the frequency of ACDC_CLK is at least 8 times of ADC_CLK.

Table 22-1 Relationship of ACDC_CLK, ADC_CLK and Sample Rates in Normal Mode

ACDC_CLK	ADC_CLK	Sample rate supported
49.152MHz	6.144MHz	12k/24k/48k/96k/192k
45.1584 MHz	5.6448 MHz	11.025k/22.05k/44.1k/88.2k/176.4k
32.768MHz	4.096MHz	8k/16k/32k/64k/128k

22.5 Application Notes

22.5.1 Hardware Application Notes:

1. Put the LDO filter cap close to the output Pin of ADC_LDO.
2. Give a Clean ground to the LDO filter cap and AVSS.

22.5.2 Software Application Notes

Steps to configure Audio ADC operates in I2S mode are as follows.

1. Program Audio_ADC_ADC_LDO to power up the HK circuit and LDO circuit.
2. Program the gain of PGA_Block and PGA_Buffer by Audio_ADC_MIC_PGA_0, Audio_ADC_MIC_PGA_1, Audio_ADC_MIC_PGA_2.
3. Program Audio_ADC_DIG_CLKEN to enable operation clocks of I2S module and ADC.
4. Program Audio_ADC_I2S_CKM to select sample rate.
5. Program Audio_ADC_ADC_0 to power up the analog ADC circuit.
6. Enable high pass filter if necessary by Programming Audio_ADC_ADC_FILTER.

Rockchip Confidential

Chapter 23 Serial Audio Interface (SAI)

23.1 Overview

The SAI controller is designed for interfacing between the AHB bus and the serial audio interface bus. The SAI is a serial link for digital audio data transfer between devices in the system. The SAI interface (Serial Audio Interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, PCM, and TDM may be addressed.
SAI is widely used in the devices such as ADC, DAC, DSP, CPU, etc. With the SAI interface, we can connect audio devices and the embedded SoC platform together and provide an audio interface solution for the system.

23.1.1 Features

- Support eight internal 32-bit wide and 32-location deep FIFOs, four for transmitting and the other for receiving audio data
- Support AHB bus interface
- Support 8 ~ 32 bits audio data transfer
- Support master and slave mode
- Support DMA handshaking interface and configurable DMA water level
- Support transmit FIFO empty, underflow, receive FIFO full, overflow interrupt and all interrupts can be masked
- Support configurable water level of transmit FIFO empty and receive FIFO full interrupt
- Support combined interrupt output
- Support 8 to 32 bit audio data left or right justified in 32-bit wide FIFO
- Support two 16-bit audio data store together in one 32-bit wide location and support four 8-bit audio data store together in one 32-bit wide location
- Support TX to RX loopback bypass mode
- Support audio protocol: I2S, PCM, TDM
- Support number of bits by frame can be configurable
- Support first active slot position in the frame is configurable
- Support up to 128 slots available with configurable size
- Support slot length 8 to 32 bits configurable
- Support slot valid data length 8 to 32 bits configurable
- Support mono audio mode
- Support slot mask configurable
- Support first active bit position in the slot is configurable
- Support MSB or LSB first serial audio data transfer
- Support configurable SCLK and FS polarity
- Support up to four lanes parallel transceivers
- Support SDI, SDO IOMUX

23.2 Block Diagram

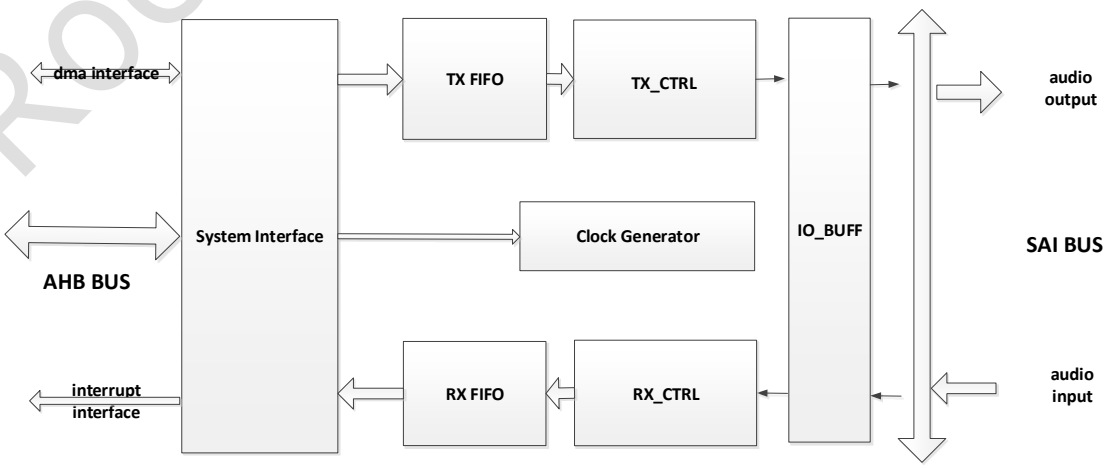

Fig. 23-1 SAI Block Diagram

Rockchip Confidencial

System Interface
The system interface implements the AHB slave operation. It contains not only control registers of transmitter and receiver inside but also interrupt and DMA handshaking interface.
Clock Generator
The Clock Generator implements clock generation function. The input source clock to the module is MCLK_SAI, and by the divider of the module, the clock generator generates SCLK and FS to transmitter and receiver.
Transmitters
The Transmitters implement transmission operation. The transmitters can act as either a master or a slave, with I2S, PCM or TDM mode surround serial audio interface.
Receiver
The Receiver implements receive operation. The receiver can act as either a master or a slave, with I2S, PCM or TDM mode stereo serial audio interface.
Transmit FIFO
The Transmit FIFO is the buffer to store transmitted audio data. The size of the FIFO is 32bits x 32.
Receive FIFO
The Receive FIFO is the buffer to store received audio data. The size of the FIFO is 32bits x 32.
IO_BUFF
SDO, SDI, LRCK_IN and LRCK_OUT register output.

23.3 Function Description

In the SAI controller, there are two types:
transmitter-master &receiver-master, transmitter-slave & receiver-slave.
In broadcasting application, the SAI controller is used as a transmitter and external or internal audio CODEC is used as a receiver. In recording application, the SAI controller is used as a receiver and external or internal audio CODEC is used as a transmitter. Either the SAI controller or the audio CODEC can act as a master or a slave, but if one is master, the other must be slave.

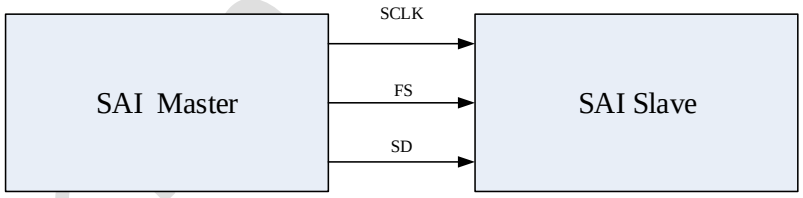

Fig.23-2 SAI transmitter-master & receiver-slave condition

When the transmitter acts as a master, it sends all signals to the receiver (the slave), and CPU controls when to send clock and data to the receiver. When acts as a slave, SD signal still goes from transmitter to receiver, but SCLK and FS signals are from the receiver (the master) to the transmitter. Based on three interface specifications, transmitting data should be ready before transmitter receives SCLK and FS signals. CPU should know when the receiver to initialize a transaction and when the transmitter to send data.
When the receiver acts as a master, it sends SCLK and FS signals to the transmitter (the slave) and receives serial data. So CPU must tell the transmitter when to start a transaction for it to prepare transmitting data then start a transfer and send clock and channel-select signals. When the receiver acts as a slave, CPU should only do initial setting and wait for all signals and then start reading data.
Before transmitting or receiving data, CPU need do initial setting to the SAI register. These includes CPU settings, SAI interface registers settings, and maybe the embedded SoC platform settings. These registers must be set before starting data transfer.
The SAI interface offers a wide set of audio protocols due to its flexibility and wide range of configurations. It can support I2S/PCM/TDM audio protocol by different configuration.

23.3.1 I2S normal mode

This is the waveform of I2S normal mode. For FS (sai_fs_rx/sai_fs_tx) signal, it goes low to

Rockchip Confidencial

indicate left channel and high to right channel. For SD (sai_sdo, sai_sdi) signal, it starts sending the first bit (MSB or LSB) one SCLK clock cycle after FS changes. The range of SD signal width is from 8 to 32bits.

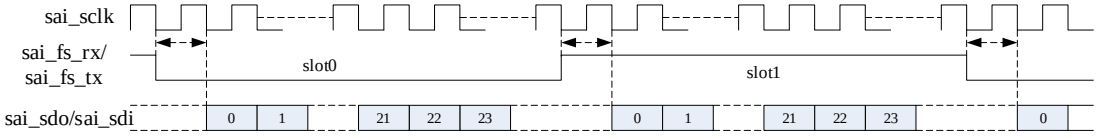

Fig.23-3 I2S Normal Mode Timing Format

23.3.2 I2S left justified mode

This is the waveform of I2S left justified mode. For FS (sai_fs_rx / sai_fs_tx) signal, it goes high to indicate left channel and low to right channel. For SD (sai_sdo/ sai_sdi) signal, it starts sending the first bit (MSB or LSB) at the same time when FS changes. The range of SD signal width is from 8 to 32bits.

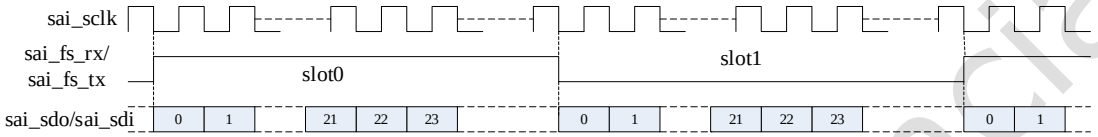

Fig.23-4 I2S Left Justified Mode Timing Format

23.3.3 I2S right justified mode

This is the waveform of I2S right justified mode. For FS (sai_fs_rx / sai_fs_tx) signal, it goes high to indicate left channel and low to right channel. For SD (sai_sdo, sai_sdi) signal, it transfers MSB or LSB first; but what is different from I2S normal or left justified mode, the last bit of the transferred data is aligned to the transition edge of the FS signal while one bit is transferred at one SCLK cycle. The range of SD signal width is from 8 to 32bits.

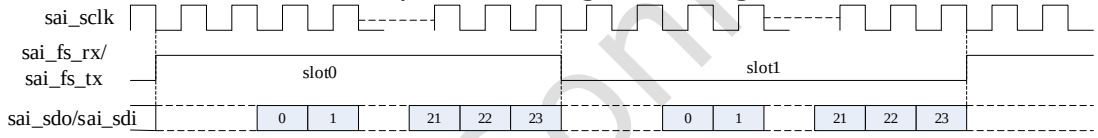

Fig.23-5 I2S Right Justified Mode Timing Format

23.3.4 PCM early mode

This is the waveform of PCM early mode. For FS (sai_fs_rx / sai_fs_tx) signal, it goes high to indicate the start of a group of audio channels. For SD (sai_sdo, sai_sdi) signal, it sends the first bit (MSB or LSB) at the same time when FS goes high. The range of SD signal width is from 8 to 32bits.

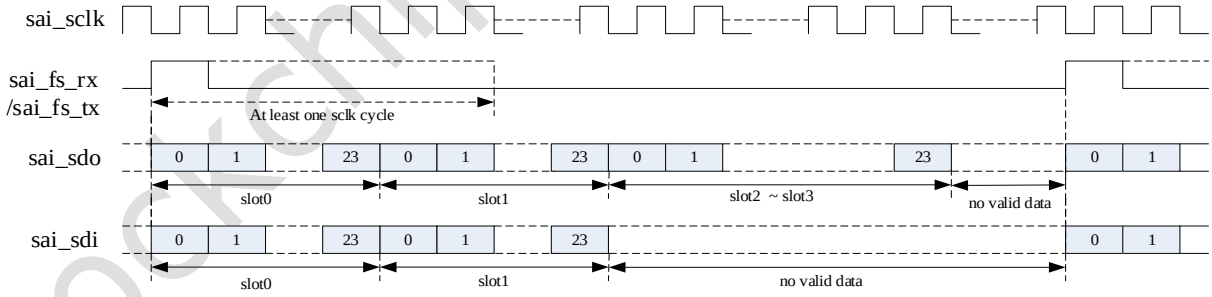

Fig.23-6 PCM Early Mode Timing Format

23.3.5 Flexibility and wide range of configurations

The SAI interface offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, PCM, and TDM may be addressed.

This is the waveform of PCM mode (SBW==VDW,FW >=SBW *SNB). For FS (sai_fs_rx / sai_fs_tx) signal, it goes high to indicate the start of a group of audio data.

Rockchip Confidential

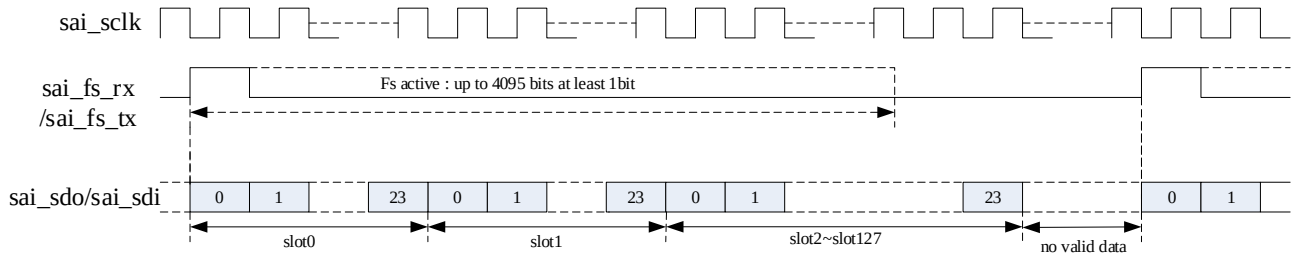

Fig.23-7 SAI PCM mode timing format

This is the waveform of I2S left mode(SBW>=VDW,FW >=SBW *SNB,VDJ==1'b1).

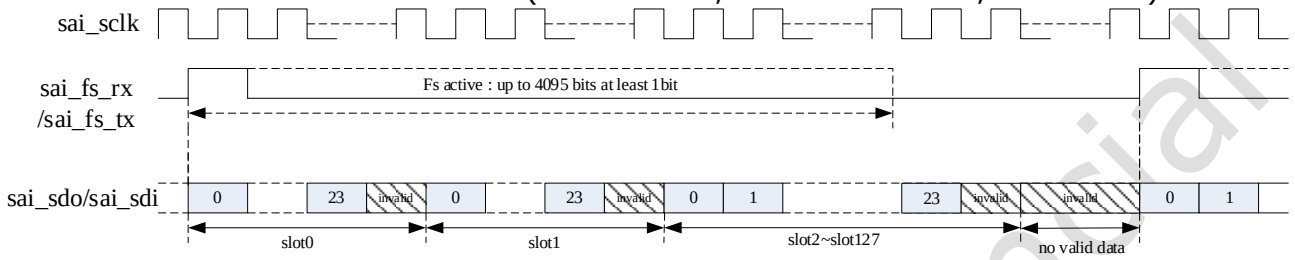

Fig.23-8 SAI I2S left mode timing format

This is the waveform of I2S right mode(SBW>=VDW,FW >=SBW *SNB,VDJ==1'b0).

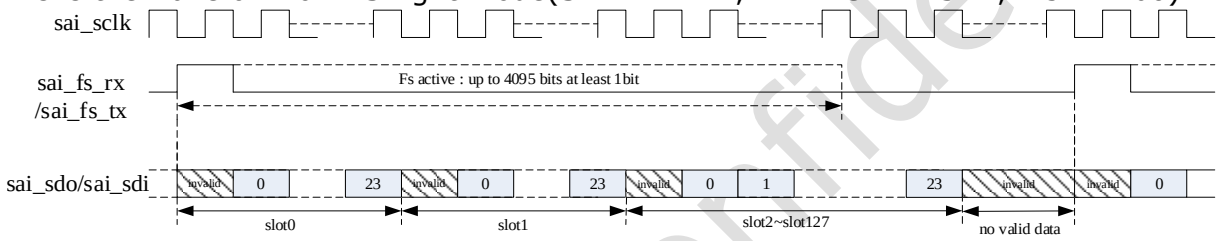

Fig.23-9 SAI I2S right mode timing format

This is the waveform of FS and SD delay time, as the posedge of FS (sai_fs_rx / sai_fs_tx) signal, we can send data at different time, The time between the FS rise edge and the first valid bit can be configured using the fs_shift register, when fs_shift[0] == 1'b0, data send at posedge of sclk,when fs_shift[0] == 1'b1, data send at negedge of sclk.

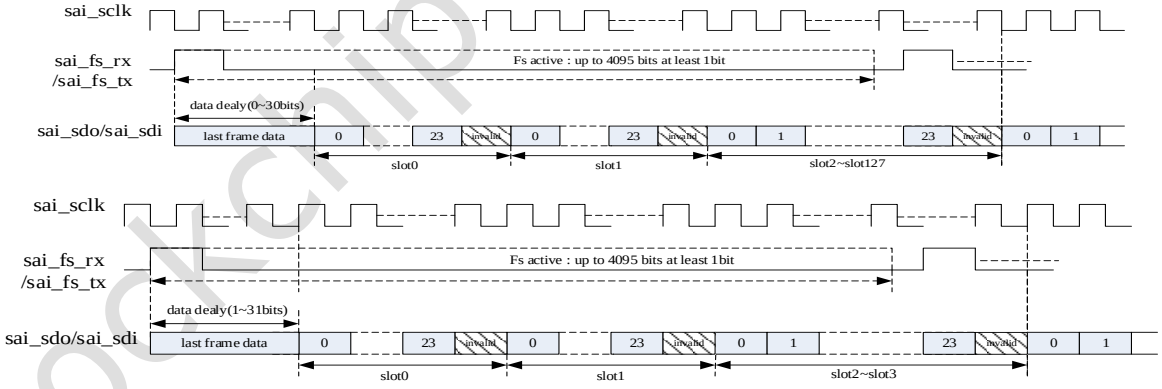

Fig.23-10 fs shift timing format

23.4 Register Description

23.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Chapter 24 Pulse Density Modulation (PDM)

24.1 Overview

The Pulse Density Modulation (PDM) is a PDM interface controller that supports mono PDM format. It integrates a clock generator driving the PDM microphone and embeds filters which decimate the incoming bit stream to obtain most common audio rates.
PDM supports the following features:

- Support one internal 32-bit wide and 128-location deep FIFOs for receiving audio data
- Support receive FIFO full, overflow interrupt and all interrupts can be masked
- Support configurable water level of receive FIFO full interrupt
- Support combined interrupt output
- Support AHB bus slave interface
- Support DMA handshaking interface and configurable DMA water level
- Support PDM master receive mode
- Support 4 paths. Each path is composed of two digital microphone channels, the PDM can be used with four stereo or eight mono microphones. Each path is enabled or disabled independently
- Support 16 ~24 bit sample resolution
- Support sample rate:
  8KHz, 16KHz, 32KHz, 64KHz, 128KHz, 11.025KHz, 22.05KHz, 44.1KHz, 88.2KHz, 176.4KHz, 12KHz, 24KHz, 48KHz, 96KHz, 192KHz
- Support two 16-bit audio data store together in one 32-bit wide location
- Support 16 to 31 bit audio data left or right justified in 32-bit wide FIFO
- Support programmable data sampling sensibility (rising or falling edge)
- Support mute function
- Support gain control
- Support 2.4MHz pdm clock

24.2 Block Diagram

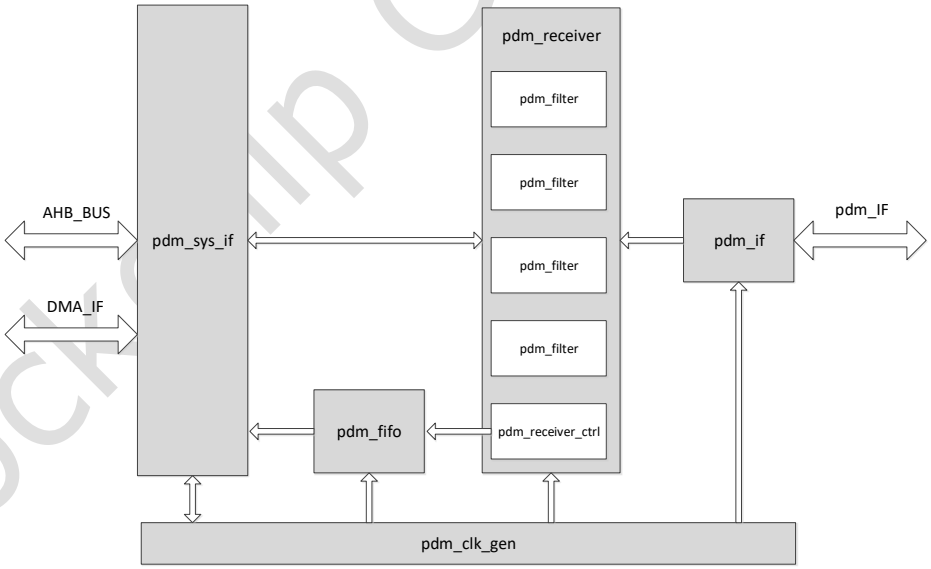

Fig. 24-1 PDM Block Diagram

System Interface
The system interface implements the APB slave operation. It contains not only control registers of receiver inside but also interrupt and DMA handshaking interface.
Receiver
The receiver can act as a decimation filter of PDM. And export PCM format data.
Receive FIFO
The Receive FIFO is the buffer to store received audio data. The size of the FIFO is 32bits x 128.
PDM interface
The PDM interface implements PDM bit streams receive operation.

Rockchip Confidential

24.3 Function Description

24.3.1 AHB Interface

There is an AHB slave interface in PDM. It is responsible for accessing registers and internal memories.

24.3.2 PDM Interface

The PDM interface is a 5-wire interface. The PDM module can support up to four external stereo and eight digital microphones.

The following figures show two cases of use of the PDM, but all configurations are possible with stereo and mono digital microphones.

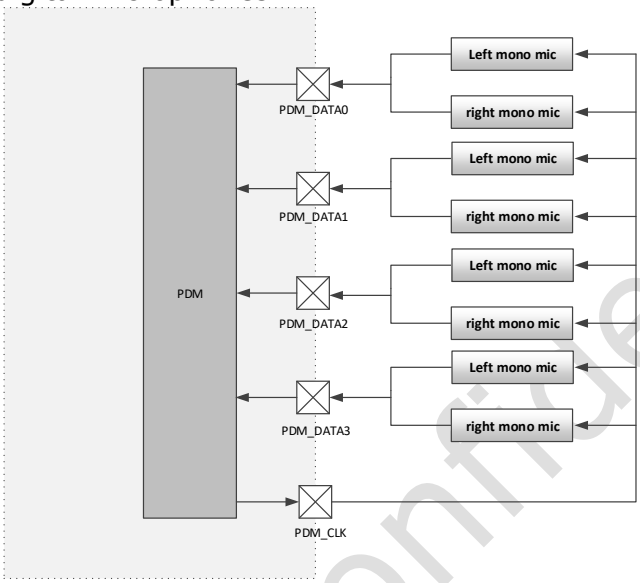

Fig. 24-2 PDM with Eight Mono MIC

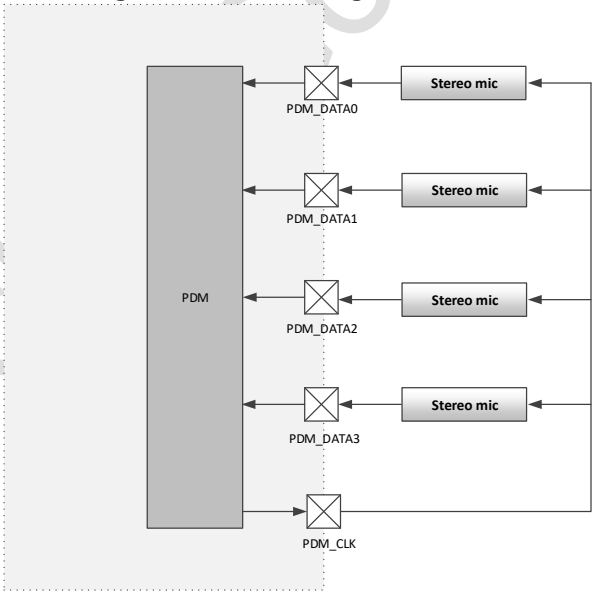

Fig. 24-3 PDM with Four Stereo MIC

The PDM interface consists of a serial-data shift clock output (PDM_CLK) and a serial data input (PDM_DATA). The clock is fanned out to both digital mics, and both digital mics' data (left channel and right channel) outputs share a single signal line. To share a single line, the digital mics tristate their output during one phase of the clock (high or low part of cycle, depending on how they are configured via their L/R input).

Rockchip Confidential

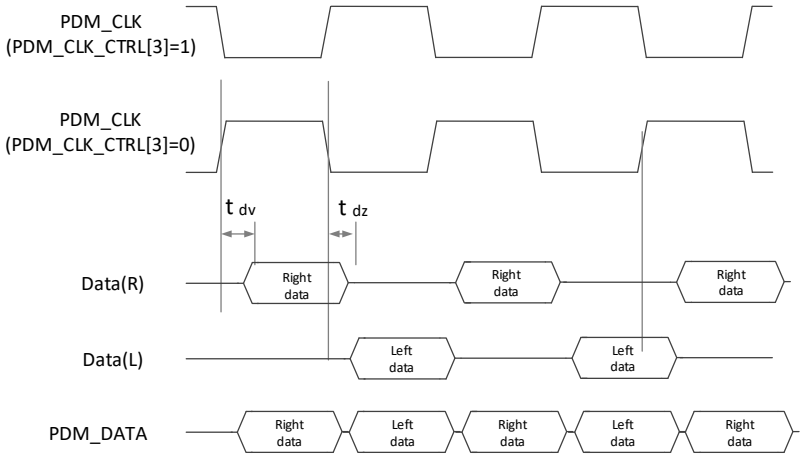

Fig. 24-4 PDM interface diagram with external MIC

24.3.3 Digital Filter

The external PDM generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the PDM. The aim of the PDM is to process data from the PDM interface, decimate and filter the data, and store the processed data in the FIFO.
The four paths are identical. Each path is composed of a left and a right channel. The PDM interface delivers eight parallel data of 1bit. Each bit goes to a filter. The aim of the filter is to limit the noise and export PCM format audio data.

24.3.4 Clock Configuration

MCLK is the source clock signal. PDM_CLK is the output clocks generated in the PDM and is fed to the external microphones. They are also the internal clock of the external microphones. User must take care about the value of PDM_CLK when selecting the source clock (MCLK).

Table 24-1 Relation between PDM_CLK and sample rate

PDM_CLK	Sample rate
3.072MHz	12KHz,24KHz,48KHz,96KHz,192KHz
2.8224MHz	11.025KHz,22.05KHz,44.1KHz,88.2KHz,176.4KHz
2.048MHz	8KHz,16KHz,32KHz,64KHz,128KHz

MCLK/PDM_CLK is more than 10;

24.4 Register Description

24.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

24.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description

Rockchip Confidencial

Chapter 25 SPDIF TX

25.1 Overview

The SPDIF transmitter is a self-clocking, serial, unidirectional interface for the interconnection of digital audio equipment for consumer and professional applications, using linear PCM coded audio samples.
It provides the basic structure of the interface. Separate documents define items specific to particular applications.
When used in a professional application, the interface is primarily intended to carry monophonic or stereophonic programmes, at a 48 kHz sampling frequency and with a resolution of up to 24bits per sample; it may alternatively be used to carry signals sampled at 32 kHz or 44.1 kHz.
When used in a consumer application, the interface is primarily intended to carry stereophonic programmes, with a resolution of up to 20 bits per sample, an extension to 24 bits per sample being possible.
When used for other purposes, the interface is primarily intended to carry audio data coded other than as linear PCM coded audio samples. Provision is also made to allow the interface to carry data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.
In all cases, the clock references and auxiliary information are transmitted along with the programme. MCLK is the operation clock of SPDIF transmitter.

Table 25-1 Maximum Frequency of MCLK for the SPDIF Transmitter

SPDIF transmitter	Maximum frequency of MCLK
SPDIF	100MHz

Each SPDIF transmitter supports following features.

- Support one internal 32-bit wide and 32-location deep sample data buffer
- Support two 16-bit audio data store together in one 32-bit wide location
- Support AHB or APB bus interface
- Support biphase format stereo audio data output
- Support DMA handshake interface and configurable DMA water level
- Support sample data buffer empty and block terminate interrupt
- Support combine interrupt output
- Support 16 to 31 bit audio data left or right justified in 32-bit wide sample data buffer
- Support 48, 44.1, 32kHz sample rate
- Support MCLK frequencies of 12.288Mhz, 8.192Mhz and 11.2896MHz
- Support 16, 20, 24 bits audio data transfer
- Support frame transmission frequency, fixed to 128 times of audio data sampling rate

25.2 Block Diagram

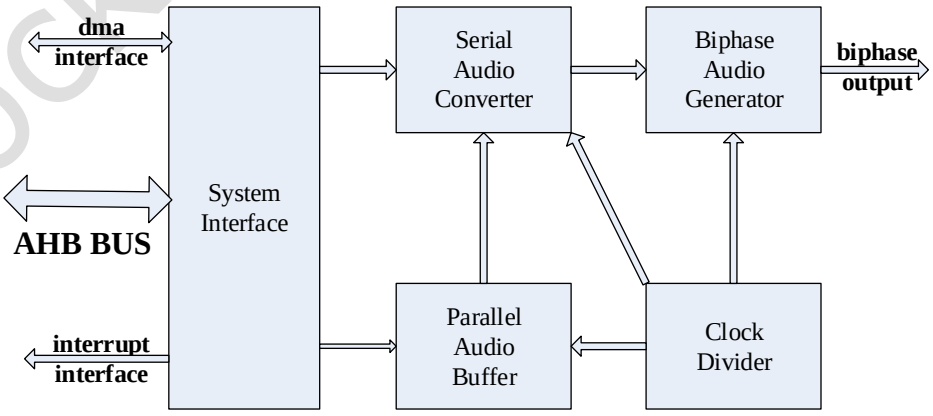

Fig.25-1 SPDIF transmitter Block Diagram

The SPDIF transmitter is composed of following module.

System Interface

The system interface implements the AHB slave operation. It contains not only control

Rockchip Confidential

registers of transmitters and receiver inside but also interrupt and DMA handshaking interface.

Clock Divider

The clock divider implements clock generation function. It divides the source clock MCLK to generate the working clock used for the digital audio data transformation and transmission.

Parallel Audio Buffer

The parallel audio buffer stores the audio data to be transmitted. The size of the FIFO is 32bits x 32.

Serial Audio Converter

The serial audio converter converts the parallel audio data from the parallel audio buffer to the serial audio data.

Biphase Audio Generator

The biphase audio generator reads serial audio data from the serial audio converter and generates biphase audio data based on IEC-60958 standard.

25.3 Function Description

25.3.1 Frame Format

A frame is uniquely composed of two sub-frames. For linear coded audio applications, the rate of transmission of frames corresponds exactly to the source sampling frequency.
In the 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive sub-frames. The first sub-frame (left channel in stereophonic operation and primary channel in monophonic operation) normally use preamble M. However, the preamble is changed to preamble B once every 192 frame to identify the start of the block structure used to organize the channel status information.
The second sub-frame (right in stereophonic operation and secondary channel in monophonic operation) always use preamble W.

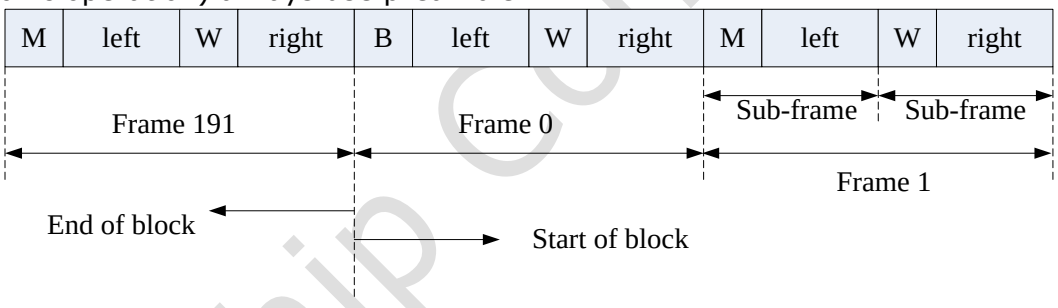

Fig.25-2 SPDIF Frame Format

In the single channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried only in the first sub-frame and may be duplicated in the second sub-frame. If the second sub-frame is not carrying duplicate data, then time slot 28 (validity flag) shall be set to logical '1' (not valid).

25.3.2 Sub-frame Format

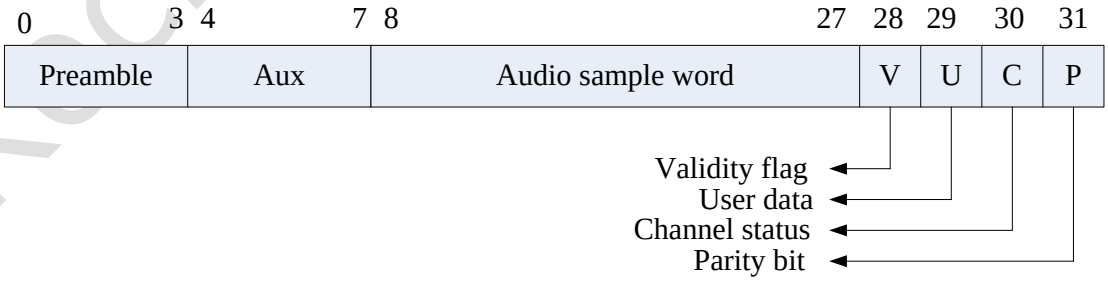

Fig.25-3 SPDIF Sub-frame Format

Each sub-frame is divided into 32 time slots, numbered from 0 to 31. Time slot 0 to 3 carries one of the three permitted preambles. Time slot 4 to 27 carry the audio sample word in linear 2's complement representation. The MSB is carried by time slot 27. When a 24-bit coding range is used, the LSB is in time slot 4. When a 20-bit coding range is used, time slot 8 to 27 carry the audio sample word with the LSB in time slot 8. Time slot 4 to 7 may be used for other application. Under these circumstances, the bits in the time slot 4 to

Rockchip Confidential

7 are designated auxiliary sample bits.
If the source provides fewer bits than the interface allows (either 24 or 20), the unused LSBs are set to a logical '0'. For a non-linear PCM audio application or a data application the main data field may carry any other information. Time slot 28 carries the validity flag associated with the main data field. Time slot 29 carries 1 bit of the user data associated with the audio channel transmitted in the same sub-frame. Time slot 30 carries one bit of the channel status words associated with the main data field channel transmitted in the same sub-frame. Time slot 31 carries a parity bit such that time slots 4 to 31 inclusive carries an even number of ones and an even number of zeros.

25.3.3 Channel Coding

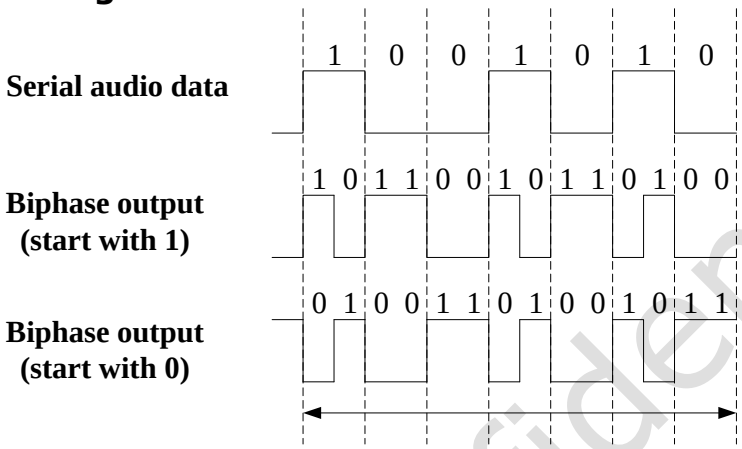

Fig.25-4 SPDIF Channel Coding

To minimize the direct current component on the transmission line, to facilitate clock recovery from the data stream and to make the interface insensitive to the polarity of connections, time slots 4 to 31 are encoded in biphase-mark.
Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical '0'. However, it is different from the first if the bit is logical '1'.

25.3.4 Preamble

Preambles are specific patterns providing synchronization and identification of the sub-frames and blocks.
To achieve synchronization within one sampling period and to make this process completely reliable, these patterns violate the biphase-mark code rules, thereby avoiding the possibility of data imitating the preambles.
A set of three preambles is used. These preambles are transmitted in the time allocated to four time slots (time slots 0 to 3) and are represented by eight successive states. The first state of the preamble is always different from the second state of the previous symbol.

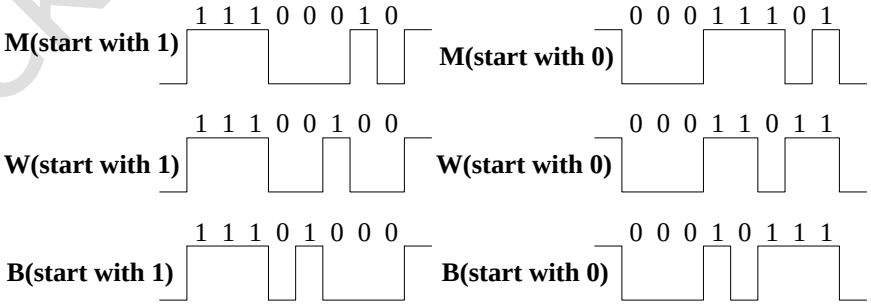

Fig.25-5 SPDIF Preamble

Like biphase code, these preambles are DC free and provide clock recovery. They differ in at least two states from any valid biphase sequence.

25.4 Register Description

25.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as

Rockchip Confidencial

follows.

Operational Base

Name	Base Address
SPDIF_TX SECURE BASE ADDRESS	0x40900000
SPDIF_TX NO-SECURE BASE ADDRESS	0x50900000

25.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
SPDIF_TX_CFGR	0x0000	W	0x00000000	Configuration Register
SPDIF_TX_SDBLR	0x0004	W	0x00000000	Sample Date Buffer Level Register
SPDIF_TX_DMACR	0x0008	W	0x00000000	DMA Control Register
SPDIF_TX_INTCR	0x000C	W	0x00000000	Interrupt Control Register
SPDIF_TX_INTSR	0x0010	W	0x00000000	Interrupt Status Register
SPDIF_TX_XFER	0x0018	W	0x00000000	Transfer Start Register
SPDIF_TX_SMPDR	0x0020	W	0x00000000	Sample Data Register
SPDIF_TX_VLDFRn	0x0060	W	0x00000000	Validity Flag Register n
SPDIF_TX_USRDRn	0x0090	W	0x00000000	User Data Register n
SPDIF_TX_CHNSRn	0x00C0	W	0x00000000	Channel Status Register n
SPDIF_TX_BURTSINFO	0x00D0	W	0x00000000	This define the channel burst info when the channel conveys non-linear PCM.
SPDIF_TX_REPETTION	0x0104	W	0x00000000	This register provides the repetition of the bitstream when channel conveys non-linear PCM. In the design, it is define the length between Pa of the two consecutive data-burst. For the same audio format, the definition is different. Please convert the actual repetition in order to comply with the design.
SPDIF_TX_BURTSINFO_SHD	0x0108	W	0x00000000	This define the channel burst info when the channel conveys non-linear PCM.
SPDIF_TX_REPETTION_SHD	0x010C	W	0x00000000	This register provides the repetition of the bitstream when channel conveys non-linear PCM.
SPDIF_TX_USRDR_SHDn	0x0190	W	0x00000000	Shadow User Data Register n

25.4.3 Detail Registers Description

SPDIF_TX_CFGR

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	MCD Fmclk/Fsdo This parameter can be calculated by Fmclk/(Fs*128). Fs is the sample frequency be wanted
15:10	RO	0x00	reserved
9	RW	0x0	PRECHANGE 0: No linear PCM length 1: 192 block
8	RW	0x0	PCMTYPE 0: linear PCM 1: non-linear PCM

Rockchip Confidential

Bit	Attr	Reset Value	Description
7	WO	0x0	CLR Write 1 to clear MCLK domain logic. Read returns zero.
6	RW	0x0	CSE 0: Disable 1: Enable The bit should be set to 1 when the channel conveys non-linear PCM
5	RW	0x0	UDE 0: Disable 1: Enable
4	RW	0x0	VFE 0: Disable 1: Enable
3	RW	0x0	ADJ 0: Right justified 1: Left justified
2	RW	0x0	HWT 0: Disable 1: Enable It is valid only when the valid data width is 16bit.
1:0	RW	0x0	VDW 00: 16bit 01: 20bit 10: 24bit 11: reserved The valid data width is 16bit only for non-linear PCM.

SPDIF_TX_SDBLR

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RW	0x00	SDBLR Contains the number of valid data entries in the sample data buffer.

SPDIF_TX_DMACR

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5	RW	0x0	TDE 0: Transmit DMA disabled 1: Transmit DMA enabled
4:0	RW	0x00	TDL This bit field controls the level at which a DMA request is made by the transmit logic. It is equal to the watermark level; that is, the dma_tx_req signal is generated when the number of valid data entries in the Sample Date Buffer is equal to or below this field value.

SPDIF_TX_INTCR

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:18	RO	0x0000	reserved
17	W1C	0x0	UDTIC Write '1' to clear the user data interrupt.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
16	W1C	0x0	BTTIC Write '1' to clear the interrupt.
15:10	RO	0x00	reserved
9:5	RW	0x00	SDBT Sample Date Buffer Threshold for empty interrupt.
4	RW	0x0	SDBEIE 0: Disable 1: Enable
3	RW	0x0	BTTIE When enabled, an interrupt will be asserted when the block transfer is finished if the channel conveys linear PCM or when the repetition period is reached if the channel conveys non-linear PCM. 0: Disable 1: Enable
2	RW	0x0	UDTIE 0: Disable 1: Enable If enabled, an interrupt will be asserted when the content of the user data register is fed into the corresponding shadow register.
1:0	RO	0x0	reserved

SPDIF_TX_INTSR

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4	RW	0x0	SDBEIS 0: Inactive 1: Active
3	RW	0x0	BTTIS 0: Inactive 1: Active
2	RW	0x0	UDTIS 0: Inactive 1: Active
1:0	RO	0x0	reserved

SPDIF_TX_XFER

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	XFER Transfer Start Register

SPDIF_TX_SMPDR

Address: **Operational Base** + offset (0x0020)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	SMPDR Sample Data Register

SPDIF_TX_VLDFRn

Address: **Operational Base** + offset (0x0060)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	VLDFR_SUB_1 Validity Flag Register 0

Rockchip Confidencial

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	VLDFR_SUB_0 Validity Flag for Subframe 0

SPDIF_TX_USRDRn

Address: **Operational Base** + offset (0x0090)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	USR_SUB_1 User Data Bit for Subframe 1
15:0	RW	0x0000	USR_SUB_0 User Data Bit for Subframe 0

SPDIF_TX_CHNSRn

Address: **Operational Base** + offset (0x00C0)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	CHNSR_SUB_1 Channel Status Bit for Subframe 1
15:0	RW	0x0000	CHNSR_SUB_0 Channel Status Bit for Subframe 0

SPDIF_TX_BURTSINFO

Address: **Operational Base** + offset (0x00D0)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	PD Preamble Pd for non-linear PCM, indicating the length of burst payload in unit of bytes or bits.
15:13	RW	0x0	BSNUM This field indicates the bitstream number. Usually the birstream number is 0.
12:8	RW	0x00	DATAINFO This field gives the data-type-dependent info.
7	RW	0x0	ERRFLAG 0: Indicates a valid burst-payload 1: Indicates that the burst-payload may contain errors

Rockchip Confidencial

Bit	Attr	Reset Value	Description
6:0	RW	0x00	DATATYPE 0000000: null data 0000001: AC-3 data 0000011: Pause data 0000100: MPEG-1 layer 1 data 0000101: MPEG-1 layer 2 or 3 data or MPEG-2 without extension 0000110: MPEG-2 data with extension 0000111: MPEG-2 AAC 0001000: MPEG-2, layer-1 low sampling frequency 0001001: MPEG-2, layer-2 low sampling frequency 0001010: MPEG-2, layer-3 low sampling frequency 0001011: DTS type I 0001100: DTS type II 0001101: DTS type III 0001110: ATRAC 0001111: ATRAC 2/3 0010000: ATRAC-X 0010001: DTS type IV 0010010: WMA professional type I 0110010: WMA professional type II 1010010: WMA professional type III 1110010: WMA professional type IV 0010011: MPEG-2 AAC low sampling frequency 0110011: MPEG-2 AAC low sampling frequency 1010011: MPEG-2 AAC low sampling frequency 1110011: MPEG-2 AAC low sampling frequency 0010100: MPEG-4 AAC 0110100: MPEG-4 AAC 1010100: MPEG-4 AAC 1110100: MPEG-4 AAC 0010101: Enhanced AC-3 0010110: MAT others: reserved

SPDIF_TX_REPETTION

Address: **Operational Base** + offset (0x0104)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	REPETTION This define the repetition period when the channel conveys non-linear PCM.

SPDIF_TX_BURTSINFO_SHD

Address: **Operational Base** + offset (0x0108)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	PD Preamble Pd for non-linear PCM, indicating the length of burst payload in unit of bytes or bits.
15:13	RO	0x0	BSNUM This field indicates the bitstream number. Usually the birstream number is 0.
12:8	RO	0x00	DATAINFO This field gives the data-type-dependent info
7	RO	0x0	ERRFLAG 0: Indicates a valid burst-payload 1: Indicates that the burst-payload may contain errors

Rockchip Confidencial

Bit	Attr	Reset Value	Description
6:0	RO	0x00	DATATYPE 0000000: null data 0000001: AC-3 data 0000011: Pause data 0000100: MPEG-1 layer 1 data 0000101: MPEG-1 layer 2 or 3 data or MPEG-2 without extension 0000110: MPEG-2 data with extension 0000111: MPEG-2 AAC 0001000: MPEG-2, layer-1 low sampling frequency 0001001: MPEG-2, layer-2 low sampling frequency 0001010: MPEG-2, layer-3 low sampling frequency 0001011: DTS type I 0001100: DTS type II 0001101: DTS type III 0001110: ATRAC 0001111: ATRAC 2/3 0010000: ATRAC-X 0010001: DTS type IV 0010010: WMA professional type I 0110010: WMA professional type II 1010010: WMA professional type III 1110010: WMA professional type IV 0010011: MPEG-2 AAC low sampling frequency 0110011: MPEG-2 AAC low sampling frequency 1010011: MPEG-2 AAC low sampling frequency 1110011: MPEG-2 AAC low sampling frequency 0010100: MPEG-4 AAC 0110100: MPEG-4 AAC 1010100: MPEG-4 AAC 1110100: MPEG-4 AAC 0010101: Enhanced AC-3 0010110: MAT others: reserved

SPDIF_TX_REPETTION_SHD

Address: **Operational Base** + offset (0x010C)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	REPETTION This register provides the repetition of the bitstream when channel conveys non-linear PCM. In the design, it is define the length between Pa of the two consecutive data-burst. For the same audio format, the definition is different. Please convert the actual repetition in order to comply with the design.

SPDIF_TX_USRDR_SHDn

Address: **Operational Base** + offset (0x0190)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	USR_SUB_1 User Data Bit for Subframe 1
15:0	RO	0x0000	USR_SUB_0 User Data Bit for Subframe 0

25.5 Interface Description

SPDIF are used to communicate with audio equipment outside this chip. Following table

Rockchip Confidencial

shows the interface of SPDIF.

Table 25-2 SPDIF TX Interface Description

Module Pin	Direction	Rockchip matrix IO	IOMUX Setting
spdif_sdo	O	RM_IO	

Notes: I=input, O=output, I/O=input/output. For the configuration of RM_IO, please refer to chapter "Rockchip Matrix IO".

25.6 Application Notes

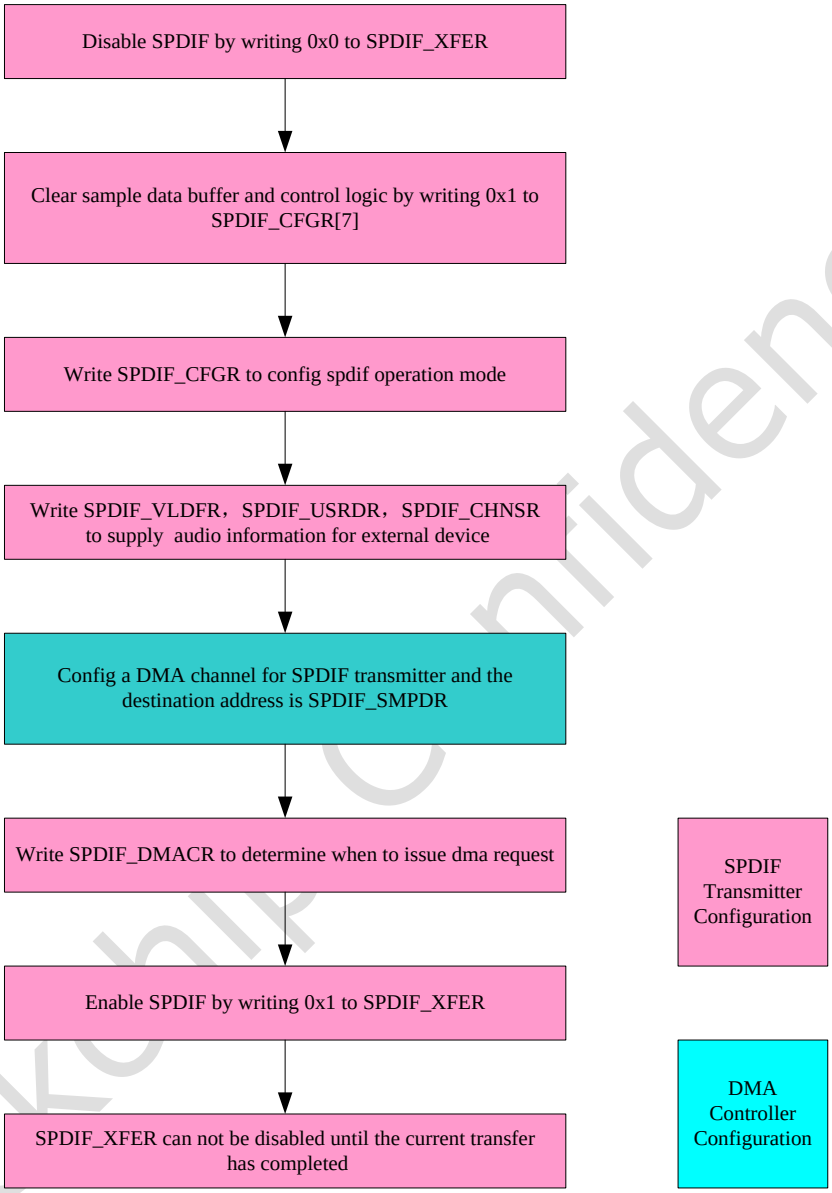

Fig.25-6 SPDIF transmitter operation flow chart

The above figure shows the operation flow of SPDIF operation. Note that the configuration register can be written only when the transfer is stopped.

Rockchip Confidencial

Chapter 26 SPDIF RX

26.1 Overview

The SPDIF receiver is a self-clocking, serial, unidirectional interface for the interconnection of digital audio equipment for consumer and professional applications, using linear PCM coded audio samples.
It provides the basic structure of the interface. Separate documents define items specific to particular applications.
When used in a professional application, the interface is primarily intended to receive monophonic or stereophonic programmes, at a 48 kHz sampling frequency and with a resolution of up to 24bits per sample; it may alternatively be used to receive signals sampled at 32 kHz or 44.1 kHz.
When used in a consumer application, the interface is primarily intended to receive stereophonic programmes, with a resolution of up to 24 bits per sample.
When used for other purposes, the interface is primarily intended to receive audio data coded other than as linear PCM coded audio samples. Provision is also made to allow the interface to receive data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.
It supports following features.

- Support AHB bus interface
- Support one internal 30-bit wide and 32-location deep FIFO for receiving audio data
- Support combined interrupt output
- Support DMA handshaking interface and configurable DMA water level
- Support linear PCM(IEC60958) and non-linear PCM(IEC61937)
- Support 16~24 bits audio sample length for liner PCM application
- Support 16 bits audio sample length for non-liner PCM application
- Support up to 192kHz sample rate with the corresponding reference clock equal to 384KHz*64*2*10, that is 245.76MHz
- Support the frequency of reference clock is at least 10 times the frequency of the biphase encoding clock, but not more than 256 times
- Support recovering clock and audio data from input bitstream

26.2 Block Diagram

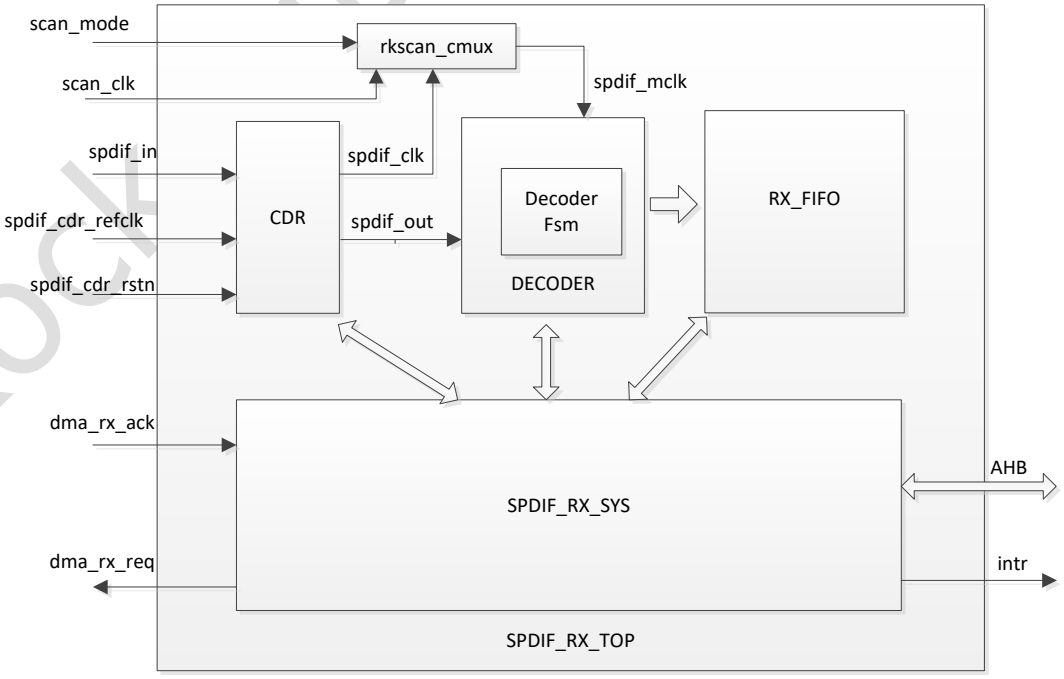

Fig.26-1 SPDIF receiver Block Diagram

The SPDIF receiver is composed of following modules.

SPDIF_RX_SYS

Rockchip Confidential

The module implements the AHB slave operation. It contains not only control registers of SPDIF receiver inside but also interrupt and DMA handshaking interface.

CDR

The CDR is short for clock and data recovery. Clock and data can be recovered from the input bitstream by using a high frequency reference clock.

DECODER

The clock recovered from the CDR is used as the working clock to decode the input bitstream such as extracting audio data, the corresponding preamble code, V/U/C/P flags and other audio information.

RX_FIFO

The RX FIFO stores the audio data extracted from input bitstream. The size of the FIFO is 30bitsx32.

26.3 Function description

26.3.1 Frame Format

SPDIF receiver follows the same protocol (IEC60958/IEC61937) as SPDIF transmitter. A frame is uniquely composed of two sub-frames. For linear coded audio applications, the rate of receiving of frames corresponds exactly to the source sampling frequency.

In the 2-channel operation mode, the samples received from both channels are arranged by time multiplexing in consecutive sub-frames. The first subframe (left channel in stereophonic operation and primary channel in monophonic operation) normally use preamble M. However, the preamble is changed to preamble B once every 192 frame to identify the start of the block structure used to organize the channel status information. The second sub-frame (right in stereophonic operation and secondary channel in monophonic operation) always use preamble W.

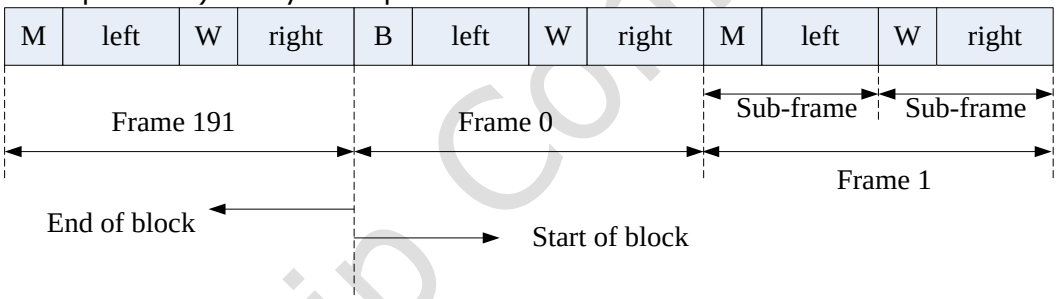

Fig.26-2 SPDIF Frame Format

In the single channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried only in the first sub-frame and may be duplicated in the second sub-frame. If the second sub-frame is not carrying duplicate data, then time slot 28 (validity flag) shall be set to logical '1' (not valid).

26.3.2 Sub-frame Format

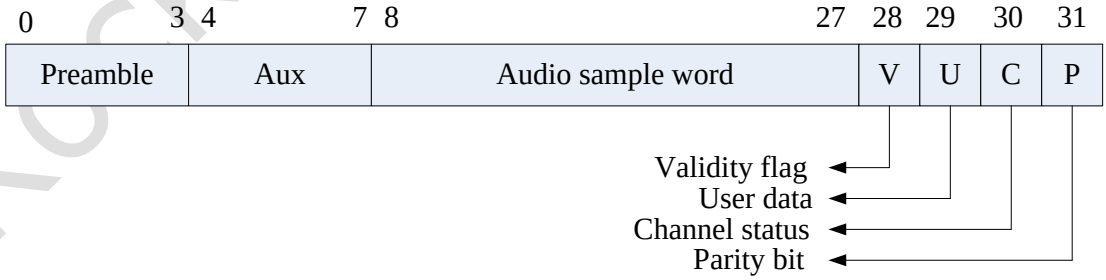

Fig.26-3 SPDIF Sub-frame Format

Each sub-frame is divided into 32 time slots, numbered from 0 to 31. Time slot 0 to 3 carries one of the three permitted preambles. Time slot 4 to 27 carry the audio sample word in linear 2's complement representation. The MSB is carried by time slot 27. When a 24-bit coding range is used, the LSB is in time slot 4. When a 20-bit coding range is used, time slot 8 to 27 carry the audio sample word with the LSB in time slot 8. Time slot 4 to 7 may be used for other application. Under these circumstances, the bits in the time slot 4 to 7 are designated auxiliary sample bits.

Rockchip Confidential

If the source provides fewer bits than the interface allows (either 24 or 20), the unused LSBs are set to a logical '0'. For a non-linear PCM audio application or a data application the main data field may carry any other information. Time slot 28 carries the validity flag associated with the main data field. Time slot 29 carries 1 bit of the user data associated with the audio channel transmitted in the same sub-frame. Time slot 30 carries one bit of the channel status words associated with the main data field channel transmitted in the same sub-frame. Time slot 31 carries a parity bit such that time slots 4 to 31 inclusive carries an even number of ones and an even number of zeros.

26.3.3 Channel Coding

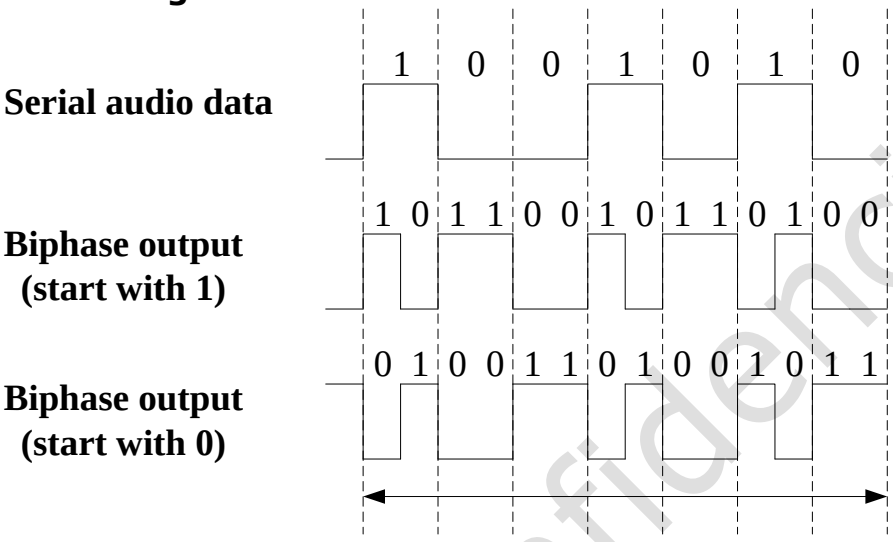

Fig.26-4 SPDIF Channel Coding

To minimize the direct current component on the transmission/receiving line, to facilitate clock recovery from the data stream and to make the interface insensitive to the polarity of connections, time slots 4 to 31 are encoded in biphase-mark.

Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical '0'. However, it is different from the first if the bit is logical '1'.

26.3.4 Preamble

Preambles are specific patterns providing synchronization and identification of the sub-frames and blocks.

To achieve synchronization within one sampling period and to make this process completely reliable, these patterns violate the biphase-mark code rules, thereby avoiding the possibility of data imitating the preambles.

A set of three preambles is used. These preambles are transmitted in the time allocated to four time slots (time slots 0 to 3) and are represented by eight successive states. The first state of the preamble is always different from the second state of the previous symbol.

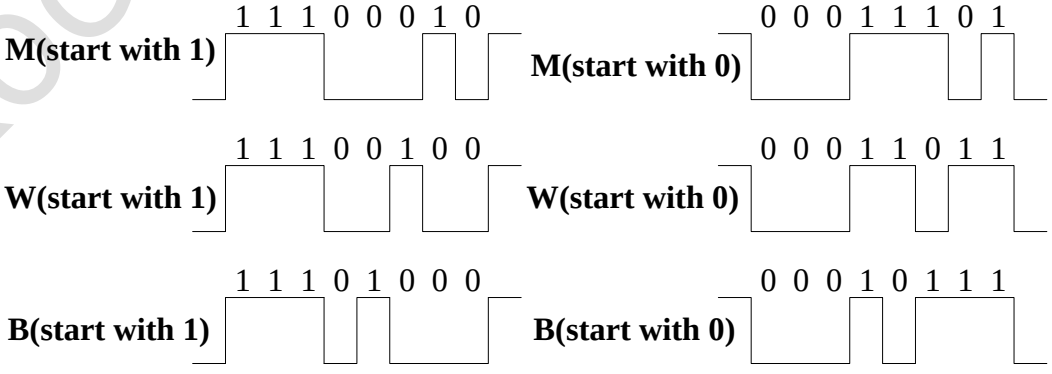

Fig.26-5 SPDIF Preamble

Like biphase code, these preambles are dc free and provide clock recovery. They differ in at least two states from any valid biphase sequence.

Rockchip Confidential

26.4 Register Description

26.4.1 Internal Address Mapping

26.4.2 Slave address can be divided into different length for different usage, which is shown as follows.

26.4.3 Registers Summary

Name	Offset	Size	Reset Value	Description
SPDIF_RX_VERSION	0x0000	W	0x23123506	Version Register
SPDIF_RX_CFGR	0x0004	W	0x00000000	Configuration Register
SPDIF_RX_CLR	0x0008	W	0x00000000	Clear Register
SPDIF_RX_CDR	0x000C	W	0x000000A1	Clock And Data Recovery Register
SPDIF_RX_CDRST	0x0010	W	0x03FF00FF	Clock And Data Recovery Status Register
SPDIF_RX_DMACR	0x0014	W	0x00000000	DMA Control Register
SPDIF_RX_FIFOCTRL	0x0018	W	0x00000000	FIFO Control Register
SPDIF_RX_INTEN	0x001C	W	0x00000000	Interrupt Enable Register
SPDIF_RX_INTMASK	0x0020	W	0x00000000	Interrupt Mask Register
SPDIF_RX_INTSR	0x0024	W	0x00000000	Interrupt Status Register
SPDIF_RX_INTCLR	0x0028	W	0x00000000	Interrupt Clear Register
SPDIF_RX_SMPDR	0x002C	W	0x00000000	Sample Data Register
SPDIF_RX_USRDRn	0x0030	W	0x00000000	User Data Register n(n=0~11)
SPDIF_RX_CHNSRn	0x0060	W	0x00000000	Channel Status Register n(n=0~11)
SPDIF_RX_CDR_TIME	0x0090	W	0x03FF03FF	CDR Time Register
SPDIF_RX_RX_STATUS	0x0094	W	0x00000000	Status Register
SPDIF_RX_BURTSINFO	0x0100	W	0x00000000	Channel Burst Info Register

26.4.4 Detail Registers Description

SPDIF_RX_VERSION

Address: Operational Base(0xFF3B0000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:0	RO	0x23123506	VER Version of SPDIF_RX.

SPDIF_RX_CFGR

Address: Operational Base(0xFF3B0000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved
2	RW	0x0	DAT 1'b0: Disable data join 1'b1: Enable data join
1	RW	0x0	TWAD 1'b0: Only audio data transmitted to FIFO. 1'b1: Block start, channel number and VUCP transmitted with audio data to FIFO.
0	RW	0x0	EN 1'b0: Disable SPDIF_RX 1'b1: Enable SPDIF_RX

SPDIF_RX_CLR

Address: Operational Base(0xFF3B0000) + offset (0x0008)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
0	RW	0x0	RXSC This is a software self-cleared bit. Write 1'b1 to clear all receive logic.

SPDIF_RX_CDR

Address: Operational Base(0xFF3B0000) + offset (0x000C)

Bit	Attr	Reset Value	Description
31:24	RW	0x00	JITTRSH CDR jitter threshold. It is valid only when BYPASS is 1'b0.
23:16	RW	0x00	MIDRGE CDR jitter middle range. It is valid only when BYPASS is 1'b0.
15:11	RO	0x00	reserved
10:9	RO	0x0	CS CDR state 2'b00: Idle state. CDR is idle and waits for rising edge of SPDIF_RX input bitstream. 2'b01: Detect state 2'b10: Measurement state 2'b11: Synchronization state
8:7	RO	0x1	JITST CDR jitter status 2'b01: Low 2'b10: High 2'b11: Normal It is valid only when BYPASS is 1'b0.
6	RO	0x0	FULL CDR FIFO full status 1'b0: Not full 1'b1: Full It is valid only when BYPASS is 1'b0.
5	RO	0x1	EMPTY CDR FIFO empty status 1'b0: Not empty 1'b1: Empty It is valid only when BYPASS is 1'b0.
4:2	RW	0x0	AVGWIN Average the non-jitter recovered clock from bitstream at a period of AVGWIN time.
1	RW	0x0	AVGSEL Select if the minimum or average number of cycles from the calculation of SPDIF_RX input bitstream pulse width. 1'b0: Minimum number of cycles 1'b1: Average number of cycles, that is (max+min)/4.
0	RW	0x1	BYPASS Write 1'b1 to enable CDR non-jitter bypass mode. It's recommended that this bit set to 1'b1. Please ensure that this bit is set to 1'b1 before starting receiving data.

SPDIF_RX_CDRST

Address: Operational Base(0xFF3B0000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:16	RW	0x03ff	NOSTRTHR The threshold counter determines the latency between input bitstream idle and exit synchronous status. Make sure that this value is large than 16'h03ff.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
15:8	RO	0x00	MAXCNT The value indicates the number of reference clock cycles to oversample the maximum pulse width of bitstream.
7:0	RO	0xff	MINCNT The value indicates the number of reference clock cycles to oversample the minimum pulse width of bitstream.

SPDIF_RX_DMACR

Address: Operational Base(0xFF3B0000) + offset (0x0014)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5	RW	0x0	RDE 1'b0: Receive DMA disabled 1'b1: Receive DMA enabled
4:0	RW	0x00	RDL This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1. That is, dma_rx_req is generated when the number of valid data entries in the sample date buffer is equal to or above this field value + 1.

SPDIF_RX_FIFOCTRL

Address: Operational Base(0xFF3B0000) + offset (0x0018)

Bit	Attr	Reset Value	Description
31:14	RO	0x00000	reserved
13:8	RO	0x00	RFL Contains the number of valid data entries in the receive FIFO.
7:5	RO	0x0	reserved
4:0	RW	0x00	RFT When the number of receive FIFO entries is more than or equal to this threshold plus 1, the receive FIFO full interrupt is triggered.

SPDIF_RX_INTEN

Address: Operational Base(0xFF3B0000) + offset (0x001C)

Bit	Attr	Reset Value	Description
31:14	RO	0x00000	reserved
13	RW	0x0	CHERRIE 1'b0: Disable 1'b1: Enable If enabled, an interrupt will generate if current data channel err.
12	RW	0x0	TYPEIE 1'b0: Disable 1'b1: Enable If enabled, an interrupt will generate if current type bit is different from previous one.
11	RW	0x0	VCGIE 1'b0: Disable 1'b1: Enable If enabled, an interrupt will generate if current valid width bit is different from previous one.
10	RW	0x0	UBCIE 1'b0: Disable 1'b1: Enable If enabled, an interrupt will generate if current user bit is different from previous one.

Chapter 27 Asynchronous Sample Rate Converter (ASRC)

27.1 Overview

ASRC converts digital audio data from one sample frequency to another. The input sample frequency can be an arbitrary fraction of the output frequency or the same frequency, but based on different clock sources. ASRC fetches audio data through AHB bus and acts as an intermediary for audio interfaces such as SAI, PDM, SPDIF, etc. With the help of ASRC, we can connect audio components with the embedded SOC platform together and provide an audio interface solution for the system.

27.1.1 Features

- Support two 4-channel ASRC0/1
- Support series mode which combines adjacent ASRC (ASRC0~1) into maximum 8-channel
- Support one 32-bit AHB-Lite bus slave interface
- Support DMA handshaking interface and configurable DMA water level
- Support up to 4-channel with same ratio for ASRC0/1, which can be set to 2/4
- Support sample rate and resample rate range from 8 to 384KHz, mainly include three typical rate groups:
  1) 8KHz, 16KHz, 32KHz, 64KHz, 128KHz
  2) 12KHz, 24KHz, 48KHz, 96KHz, 192KHz, 384KHz
  3) 11.025KHz, 22.05KHz, 44.1KHz, 88.2KHz, 176.4KHz, 352.8KHz
- Support up-conversion, down-conversion, and 1:1 asynchronous conversion
- Support conversion ratio ranging from 1:8 (down) to 8:1 (up) with 22-bit resolution
- Support low deterministic latency related to ratio
- Support hard mute and soft mute
- Support typical THD+N below -120dB
- Support real-time transmission mode, which transmits or receives audio data from either audio component or memory with ratio tracking
- Support memory fetch mode, which transmits or receives audio data from memory with manual ratio without tracking
- Support input/output 16/20/24-bit wide audio data transfer
- Support two 16-bit audio data store together in one 32-bit wide location
- Support audio data left or right justified in 32-bit wide FIFO
- Support half channels internal 48-bit wide and 16-location deep FIFOs for transmitting, and half channels 48-bit wide and 64-location deep FIFOs for receiving audio data
- Support fixed and incremental address access to transmit and receive FIFOs
- Support ratio_init/update_done, asrc_out_start, conv_done/error, fifo_in_empty/full, fifo_out_empty/full, ratio/src_lrck/dst_lrck_unlock interrupt, which can be masked
- Support combined interrupt output

27.2 Block Diagram

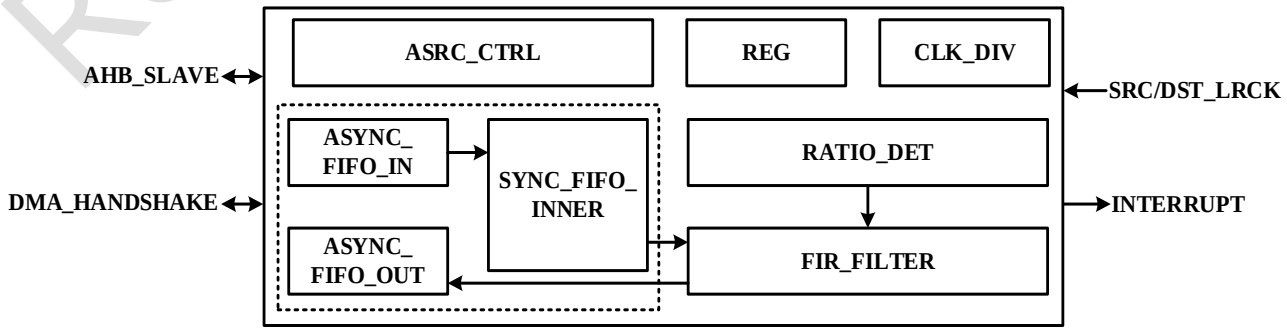

Fig. 27-1 ASRC Block Diagram

System Interface

Rockchip Confidential

System interface implements the interactions with SOC platform. It contains not only AHB slave interface which controls registers and audio data transfer, but also LRCK interface, DMA handshaking interface and interrupt interface.

Clock Divider Block (CLK_DIV)

Clock divider block implements clock frequency divide function. The source clock of the divider block are src_lrck and dst_lrck, and by the divider, it generates clocks with the same frequency as sample rate or resample rate.

Register Block (REG)

Register block is responsible for the main ASRC functionality including control, status and interrupt generation.

Controller Block (ASRC_CTRL)

Controller block is the main control block of variable sampling filter, its main functions include filtering output judgment, coefficient position calculation and interpolation filtering.

Ratio Detector Block (RATIO_DET)

The main function of ratio detector block is to initialize and track ratio related parameters. In the initialization stage, related parameters is fetched directly from register configuration. Then in the tracking stage, ratio tracking is realized through periodic detection of src_lrck and dst_lrck. In the meantime, the water level of output FIFO is monitored for negative feedback adjustment.

FIR Block (FIR_FILTER)

FIR block acts as a poly-phase filter, which interpolates the correct phase and applies the calculated filter coefficients to the set of input samples to form an output sample.

Inner FIFO Block (SYNC_FIFO_INNER)

Inner FIFO block is the buffer to store audio data for FIR Filter. The size is 48bits x 512 and the number is half channels.

Input FIFO Block (ASYNC_FIFO_IN)

Input FIFO block is the buffer to store received audio data. The size is 48bits x 16 and the number is half channels.

Output FIFO Block (ASYNC_FIFO_OUT)

Output FIFO block is the buffer to store transmitted audio data. The size is 48bits x 64 and the number is half channels.

27.3 Function Description

Firstly, we define two basic modes of ASRC, memory fetch mode and real-time transmission mode. Then to enhance throughput, we define an enhancement mode called series mode, which can combine adjacent ASRCs together.

27.3.1 Memory Fetch Mode

In memory fetch mode, ASRC is working based on manual ratio, ratio tracking is disabled, so src_lrck or dst_lrck is unused. ASRC acts as peripheral when transmitting or receiving audio data from memory, so both dma_tx_req and dma_rx_req are started by ASRC. The faster the frequency of working clock, the faster the conversion will be completed.

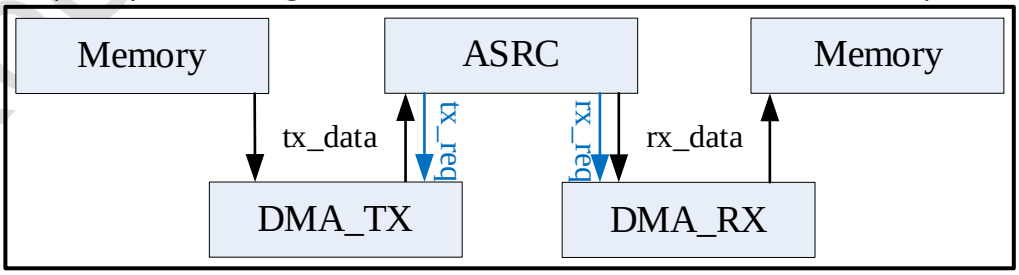

Fig. 27-2 ASRC Memory Fetch Mode Structure

Based on memory fetch mode, we extends a new sub-pattern called loop mode. With loop mode, multiple discrete audio files can be converted by only one configuration, or one continuous audio files can be split into multiple parts and converted by one configuration. The most significant application of loop mode is to convert more channel real-time audio data than ASRC defined by time division multiplexing. Audio data in the middle part of file

Rockchip Confidential

should be recalled additionally for continuous output.

27.3.2 Real-time Transmission Mode

In real-time transmission mode, ASRC is working based on both manual ratio and tracking ratio, ratio tracking is enabled, so src_lrck or dst_lrck is needed. The faster the frequency of working clock, the more precise the tracking will be completed. Real-time transmission mode can be divided into four sub-patterns based on the component types at the source and destination ends, called MEM2MEM, MEM2DST, SRC2MEM and SRC2DST for short.

- **MEM2MEM**

In MEM2MEM mode, memory serves as both source and destination component. ASRC acts as peripheral when receiving audio data from memory or transmitting audio data to memory. Hence, both dma_tx_req and dma_rx_req are started by ASRC. Besides, both src_lrck and dst_lrck originate from CRU.

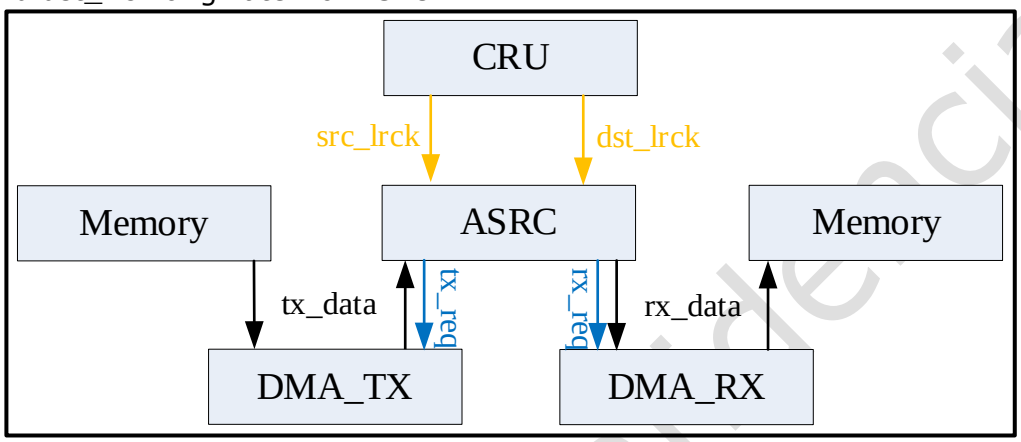

Fig. 27-3 ASRC MEM2MEM Mode Structure

- **MEM2DST**

In MEM2DST mode, memory serves as source component, and audio component serves as destination component. ASRC acts as peripheral when receiving audio data from memory, but as memory when transmitting audio data to peripheral. Hence, dma_tx_req is started by ASRC, but dma_rx_req is started by audio component. Besides, src_lrck originates from CRU, but dst_lrck originates from audio component.

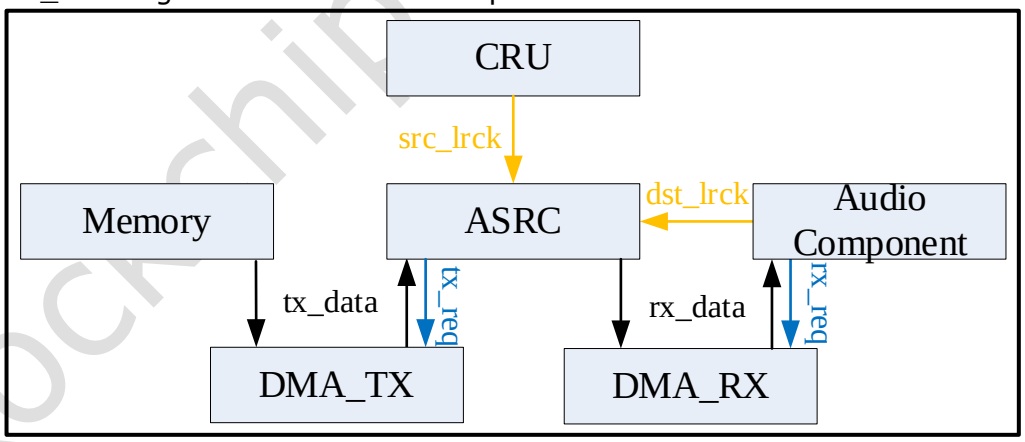

Fig. 27-4 ASRC MEM2DST Mode Structure

- **SRC2MEM**

In SRC2MEM mode, audio component serves as source component, and memory serves as destination component. ASRC acts as memory when receiving audio data from audio component, but as peripheral when transmitting audio data to memory. Hence, dma_tx_req is started by audio component, but dma_rx_req is started by ASRC. Besides, src_lrck originates from audio component, but dst_lrck originates from CRU.

Rockchip Confidential

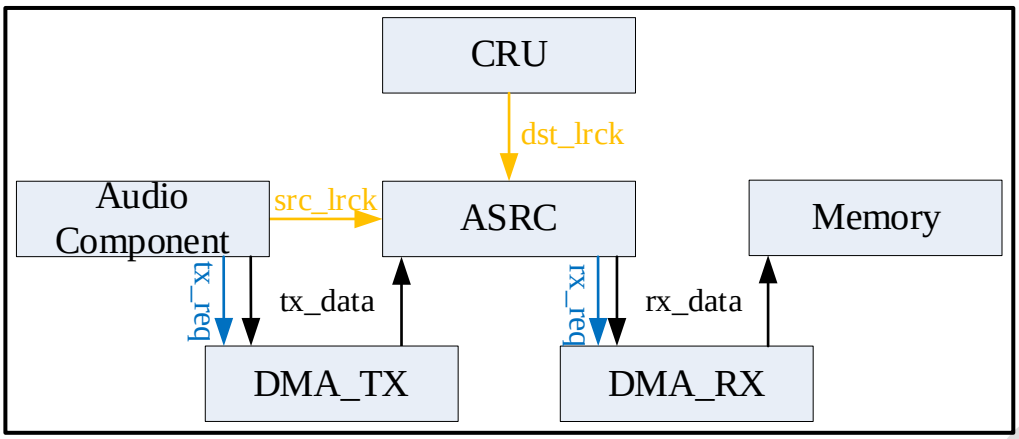

Fig. 27-5 ASRC SRC2MEM Mode Structure

- **SRC2DST**

In SRC2DST mode, audio component serves as both source component and destination component. ASRC acts as memory when receiving audio data from audio component or transmitting audio data to audio component. Hence, both dma_tx_req and dma_rx_req are started by audio component. Besides, both src_lrck and dst_lrck originate from audio component.

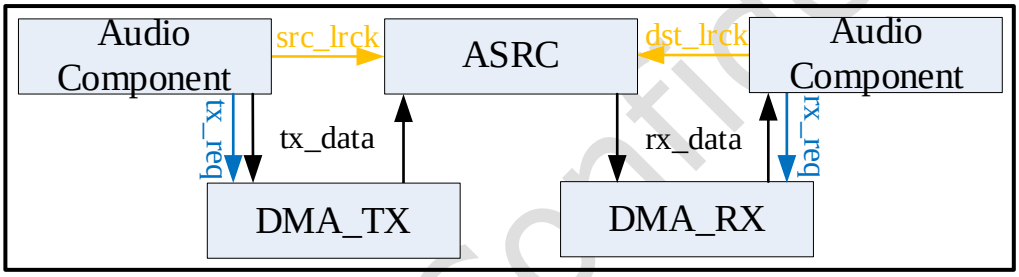

Fig. 27-6 ASRC SRC2DST Mode Structure

27.3.3 Series Mode

In series mode, adjacent ASRCs can be combined together to enhance throughput. We can appoint the ASRC at the front as master and other ASRCs as slave. All combined ASRCs can be viewed as a whole and interact with the outside world using the interface of master only. We can take MEM2MEM series mode as an example in the following figure. Note, the letter M stands for master and the letter S stands for slave.

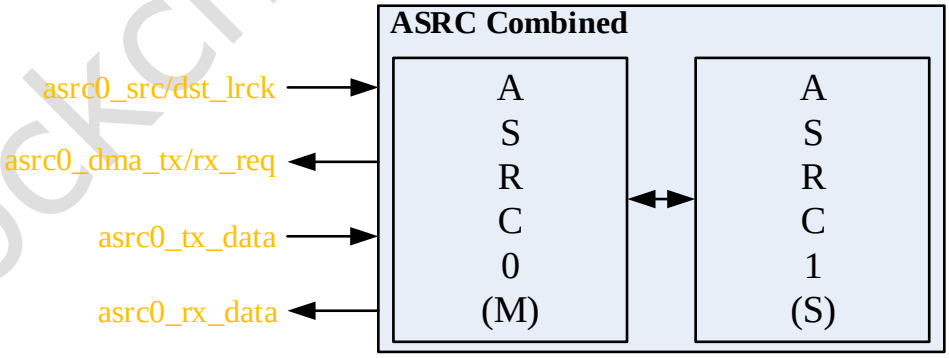

Fig. 27-7 ASRC MEM2MEM Series Mode Structure

In RK3506, ASRC0 and ASRC1 can be combined together into maximum 8-channel.

27.3.4 ASRC Latency

In real-time transmission mode, the latency of ASRC is determined by the phase delay of the FIR filter and fill level of the FIFO. For any given configuration and ratio, the latency of ASRC is fixed as follow:

Latency = phase delay + FIFO delay

Where phase delay equals 32 input sample periods when ratio is not more than one, or equals (32*ratio) input sample periods otherwise. FIFO delay equals (asrc_in_thresh+1)

Rockchip Confidential

input sample periods plus (asrc_out_thresh+1) output sample periods.
In memory fetch mode, the conversion will be completed as fast as possible according to working clock only, regardless of src_lrck and dst_lrck, the latency can be ignored.

27.4 Register Description

27.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
ASRC4CH0 base address	0xFF3C0000
ASRC4CH1 base address	0xFF3D0000

18:0	RW	0x2ee00	sample_rate Sample rate ranges from 8KHz to 384KHz.

ASRC_RESAMPLE_RATE

Address: **Operational Base** + offset (0x0028)

Bit	Attr	Reset Value	Description
31:19	RO	0x0000	reserved
18:0	RW	0x2ee00	resample_rate Resample rate ranges from 8KHz to 384KHz.

Rockchip Confidential

ASRC_TRACK_PERIOD

Address: **Operational Base** + offset (0x002C)

Bit	Attr	Reset Value	Description
31:28	RO	0x0	reserved
27:16	RW	0x000	ratio_track_div Ratio track divider, which scale down the frequency of src_lrck and dst_lrck for higher precision of ratio tracking.
15:12	RO	0x0	reserved
11:0	RW	0x3ff	ratio_track_period Ratio track period, which means tracking information updates every (ratio_track_period+1)*(ratio_track_div+1) clock.

ASRC_RATIO_MARGIN

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:22	RO	0x000	reserved
21:0	RW	0x3fffff	ratio_margin Ratio margin with fixed-point 22Q22, which shows decimal part of ratio. Ratio unlock occurs when the difference between ratio_st and manual_ratio exceeds ratio_margin.

ASRC_LRCK_MARGIN

Address: **Operational Base** + offset (0x0034)

Bit	Attr	Reset Value	Description
31	RW	0x0	dst_lrck_margin_dis Dst_lrck drift detect disable. 1'b0: Disable 1'b1: Enable
30:16	RW	0x7fff	dst_lrck_margin Dst_lrck drift margin. Dst_lrck unlock occurs when the variation of dst_lrck exceeds dst_lrck_margin.
15	RW	0x0	src_lrck_margin_dis Src_lrck drift detect disable. 1'b0: Disable 1'b1: Enable
14:0	RW	0x7fff	src_lrck_margin Src_lrck drift margin. Src_lrck unlock occurs when the variation of src_lrck exceeds src_lrck_margin.

ASRC_FETCH_LEN

Address: **Operational Base** + offset (0x0040)

Bit	Attr	Reset Value	Description
31:24	RW	0x3f	mem_fetch_ext_cnt Memory fetch extend counter, is used only when asrc_mode equal 1. It extends the interval of filter operation, which works only when series_en not equal 0.
23:20	RO	0x0	reserved
19:0	RW	0x00000	fetch_length Memory fetch length, is used only when asrc_mode equal 1. It indicates the number of input data per channel. As input data is written by AHB bus in word, if the number written is called INPUT_WORD_NUM, the equation is as follows: fetch_length=INPUT_WORD_NUM*(IFMT+1)/(2*(chan_num+1))

ASRC_DMA_THRESH

Address: **Operational Base** + offset (0x0050)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:26	RW	0x3b	asrc_pos_thresh Output FIFO positive thresh, unit channel_num. Exceed positive occurs once the number of valid data entries in the output FIFO is above this field value. Note, asrc_pos_thresh had better be higher than 59.
25:20	RW	0x04	asrc_neg_thresh Output FIFO negative thresh, unit channel_num. Exceed negative occurs once the number of valid data entries in the output FIFO is below this field value. Note, asrc_neg_thresh had better be lower than 4.
19:18	RO	0x0	reserved
17:12	RW	0x0b	asrc_out_thresh ASRC start output thresh, unit channel_num. Output will start once the number of valid data entries in the output FIFO is above this field value. Note, asrc_out_thresh must be higher than dma_rx_thresh.
11:8	RW	0x3	asrc_in_thresh ASRC start conversion thresh, unit channel_num. Conversion will start once the number of valid data entries in the input FIFO is above this field value. Note, asrc_in_thresh must be no more than dma_tx_thresh.
7:4	RW	0x3	dma_rx_thresh DMA rx request thresh, unit channel_num. The watermark level = dma_rx_thresh+1; that is, dma_rx_req is generated when the number of valid data entries in the output FIFO is equal to or above this field value + 1.
3:0	RW	0x3	dma_tx_thresh DMA tx request thresh, unit channel_num. It is equal to the watermark level; that is, the dma_tx_req signal is generated when the number of valid data entries in the input FIFO is equal to or below this field value.

ASRC_INT_CON

27.5 Application Notes

27.5.1 LRCK Multiplexing Setting

There are src_lrck and dst_lrck interface which source from audio component or CRU. In real-time transmission mode, the following multiplexing selector need to be set.

Table 27-1 ASRC4ch0 Src_lrck Selector Description

Register Name	MUX Setting	LRCK Source Select
CRU_CLKSEL_CON47	3:0	5'd0: mclk_asrc0 5'd1: mclk_asrc1 5'd2: mclk_asrc2 5'd3: mclk_asrc3 5'd4: mclk_spdiftx_to_asrc 5'd5: mclk_spdifrx_to_asrc 5'd6: clkout_pdm 5'd7: sai0_fs 5'd8: sai1_fs 5'd9: sai2_fs 5'd10: sai3_fs 5'd11: sai4_fs

Table 27-2 ASRC4ch0 Dst_lrck Selector Description

Register Name	MUX Setting	LRCK Source Select

CRU_CLKSEL_CON47	15:12	5'd0: mclk_asrc0 5'd1: mclk_asrc1 5'd2: mclk_asrc2 5'd3: mclk_asrc3 5'd4: mclk_spdiftx_to_asrc

Rockchip Confidencial

Register Name	MUX Setting	LRCK Source Select
		5'd5: mclk_spdifrx_to_asrc 5'd6: clkout_pdm 5'd7: sai0_fs 5'd8: sai1_fs 5'd9: sai2_fs 5'd10: sai3_fs 5'd11: sai4_fs

27.5.2 LRCK Divider Setting

In real-time transmission mode, src_lrck and dst_lrck are treated as data and sampled by working clock to realize periodic detection for ratio tracking. Frequency of src_lrck must be the same as sample rate of audio data, and frequency of dst_lrck must be the same as resample rate of audio data. To guarantee this, two clock dividers are integrating into ASRC. In the following condition, the corresponding divider ought to be set and we ought to wait for the generated clock to stabilize before starting ASRC.

- Using PDM as source component, set src_lrck_div_con to (pdm_oversample_rate-1)
- Using SPDIF_RX as source component, set src_lrck_div_con to 127
- Using SPDIF_TX as destination component, set dst_lrck_div_con to (128*spdiftx_div-1)

27.5.3 Tracking Period Setting

In real-time transmission mode, ratio tracking is enabled. Tracking period is determined by the value of ratio_track_period and ratio_track_div, which means track information updates every (ratio_track_period+1)*(ratio_track_div+1) working clock. The longer the period, the more precise the tracking. Besides, the following format must be meet to ensure ratio resolution:

(ratio_track_period+1)*(ratio_track_div+1) >=

Twclk*Fsrc_lrck*(1/Resolution+Fsrc_lrck/(Resolution*Fdst_lrck)+1)

Where Twclk is the period of working clock, Resolution is the bit wide of ratio, Fsrc_lrck is the frequency of src_lrck, and Fdst_lrck is the frequency of dst_lrck. Note that the smaller ratio_track_div is, the better, given the equation.

Besides, once lrck sources from CRU for audio component like USB or MAC, the fractional divider in the clock path of src_lrck or dst_lrck ought to be used for seamless switching. In this scenario, tracking period must be an integer multiple of the frequency division period, to guarantee ratio tracking accuracy.

27.5.4 DMA Setting

For transmitting data to ASRC and receiving data from ASRC, two DMA channels are need called DMA_TX and DMA_RX here. DMA mode used for various ASRC mode is shown below.

Table 27-5 ASRC DMA Mode Description

ASRC Mode	DMA_TX	DMA_RX
Memory Fetch Mode	M2P	P2M
MEM2MEM	M2P	P2M
MEM2DST	M2P	M2P
SRC2MEM	P2M	P2M
SRC2DST	P2M	M2P

In a word, once interacting with audio component, ASRC acts as memory and audio component issues DMA request, once interacting with memory, ASRC acts as peripheral and issues DMA request according to dma_tx_thresh and dma_rx_thresh.

Both dma_tx_thresh and dma_rx_thresh are in the unit of chan_num. That is, the relation between real DMA burst (called dma_tx/rx_burst) and dma_tx/rx_thresh is shown below:

dma_tx_thresh = dma_tx_burst*(IFMT+1)/(chan_num+1)/2-1

dma_rx_thresh = dma_rx_burst*(OFMT+1)/(chan_num+1)/2-1

27.5.5 Memory Fetch Mode Setting

- **Setting order**
  - Set and start DMA_TX and DMA_RX.
  - Set and start ASRC.

Rockchip Confidential

- **ASRC start Flow**
  - Set used channel number, chan_num.
  - Set data format, OFMT, IFMT, OWL, IWL, OSJM and ISJM.
  - Set manual_ratio, sample_rate and resample_rate.
  - Set thresh, dma_rx_thresh, dma_tx_thresh, asrc_out_thresh and asrc_in_thresh;
  - Set asrc_mode to 1.
  - Set conversion length, fetch_length.
  - Set conv_done_en to enable conversion done interrupt.
  - In loop mode, set continuous conversion times (loop_times), file channel number divided by used channel number (chan_times), file type (loop_start/end_mode) and conversion interval (loop_gap_thresh), then enable loop_en.
  - Set asrc_en to enable ASRC.
- **ASRC end Flow**
  - Wait for conv_done and DMA_RX done interrupt.
  - Set asrc_en to disable ASRC.

27.5.6 Real-time Transmission Mode Setting

- **Setting order**
  - Set the source of src_lrck and dst_lrck.
  - Set src_lrck_div_con, src_lrck_div_en, dst_lrck_div_con, dst_lrck_div_en if needed.
  - Set and start DMA_TX and DMA_RX.
  - Set and start ASRC; ASRC must be set before source and destination component to make sure audio data is aligned by channel.
  - Set and start source component in the mode SRC2MEM or SRC2DST.
  - Set and start destination component in the mode MEM2DST or SRC2DST. Destination component had better start when asrc_out_start interrupt assert which means destination data is ready.
- **ASRC start Flow**
  - Set used channel number, chan_num.
  - Set data format, OFMT, IFMT, OWL, IWL, OSJM and ISJM.
  - Set manual_ratio, sample_rate and resample_rate.
  - Set thresh, dma_rx_thresh, dma_tx_thresh, asrc_out_thresh and asrc_in_thresh.
  - Set asrc_mode to 0; set real_time_mode.
  - Set ratio_track_period and ratio_track_div.
  - Set ratio_track_dis to disable ratio tracking, ratio_filt_dis to disable ratio tracking filter, or ratio_exc_dis to disable ratio tracking feedback if needed.
  - Set conv_done_en to enable conversion done interrupt.
- **ASRC end Flow**
  - Set asrc_in_stop to end conversion if source component stop.
  - Set asrc_out_stop to end conversion if destination component stop.
  - Wait for conv_done and DMA_RX done interrupt.
  - Set asrc_en to disable ASRC.

27.5.7 Series Mode Setting

In series mode, we can set each ASRC as mentioned above. Several additional setting is needed shown as follow:

- Set series_en to appoint master and slave; Note that series_en can’t be set if series mode is disabled.
- Set series_post_end to appoint the last slave if memory fetch mode is selected.
- Set asrc_en of the series master at the end after all other configurations are set.

The following table shows all the cascading combinations in RK3506. Note, the letter M stands for master and the letter S stands for slave.

Table 27-6 ASRC Series Description

Series Setting	Series Combination
ASRC0_ASRC_CON[13:12]=2’h1 ASRC1_ASRC_CON[13:12]=2’h2	ASRC0(M), ASRC1(S)

Chapter 28 Flexible Serial Peripheral Interface（FSPI）

28.1 Overview

The FSPI is a flexible serial peripheral interface host controller to interface with external device.

The FSPI supports the following features:

- Support various vendor devices with flexible command sequencer engine
  - Serial NOR Flash
  - Serial NAND Flash
  - Serial pSRAM
  - Serial SRAM
- Support SDR mode
- Support Single/Dual/Quad IO mode
- Support a 32-bit AHB slave to read and write controller register bank and initiate command sequence, including transfer data from/to external device indirectly
- Support a 32-bit AHB master with embedded DMA engine to transfer data from/to external device indirectly
- Support independent clock for system bus HCLK and controller core SCLK
- Support maskable interrupts generation
- Support sampling clock with optionally configurable delay line
- Support 1 CS# operation

28.2 Block Diagram

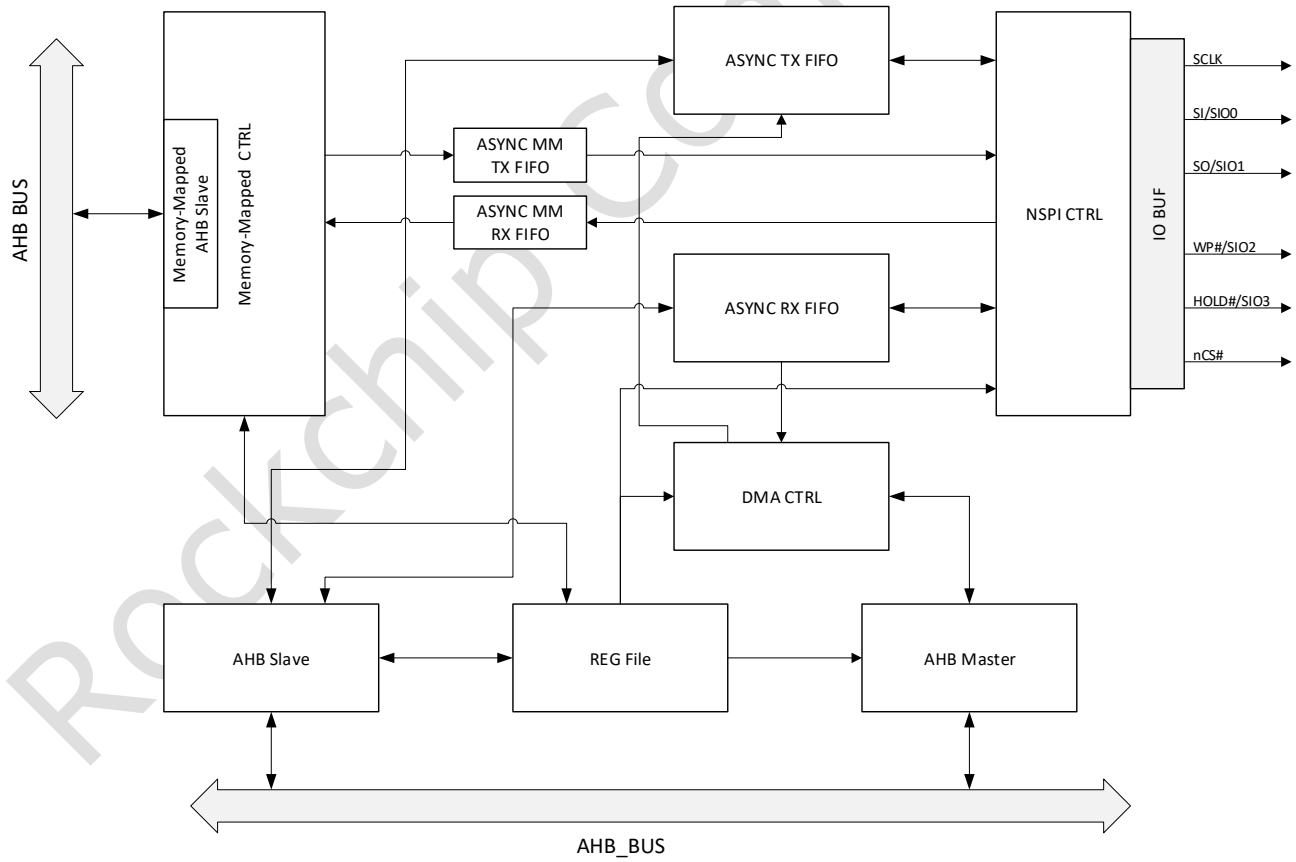

Fig. 28-1 FSPI Architecture

Memory-Mapped AHB slave is available when XIP feature is present. In current chip, this feature is not provided.

Rockchip Confidential

28.3 Function Description

28.3.1 AHB Slave

The AHB slave block is used to configure the register of controller to generate flexible command sequence, process the interrupt exception, target various device feature and AC timing specification. It is also used to write CMD/ADDR/DATA to TX FIFO and read DATA from RX FIFO which buffer the DATA from external device.

28.3.2 AHB Master

When the embedded DMA CTRL is used to transfer DATA, the AHB master is used to transfer data to other system region, such as internal SRAM, peripheral, external DRAM.

28.3.3 REG File

The REG File is configurable register bank to control the store the static configuration and dynamic status of controller.

28.3.4 DMA CTRL

The block is responsible for splitting a long length transfer trans into AHB bus transaction and interfacing with ASYNC TX or RX FIFO.

28.3.5 FIFO

There are four FIFO in the FSPI controller. ASYNC TX FIFO and ASYNC RX FIFO is for normal transaction that initiated by command sequence driver. The ASYNC MM (Memory-Mapped) TX FIFO and ASYNC MM (Memory-Mapped) RX FIFO is only used to buffer DATA from or to external device initiated by system bus master directly.

28.3.6 NSPI CTRL

Sequence decode engine which generates specialized timing sequence for various device. The NSPI decode the transaction from TX FIFO and Memory-Mapped Controller and convert it to relative CMD/ADDR/DATA frame based on the configuration.

28.4 Register Description

28.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

28.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
FSPI_CTRL0	0x0000	W	0x00000000	Control Register for CS0 Device
FSPI_IMR	0x0004	W	0x000001FF	Interrupt Mask Register
FSPI_ICLR	0x0008	W	0x00000000	Interrupt Clear Register
FSPI_FTLR	0x000C	W	0x00001010	FIFO Threshold Level Register
FSPI_RCVR	0x0010	W	0x00000000	FSPI Recover Register
FSPI_AX0	0x0014	W	0x00000000	FSPI Auxiliary Data Value for CS0 Device
FSPI_ABIT0	0x0018	W	0x00000000	Extend Address Bits for CS0 Device
FSPI_ISR	0x001C	W	0x00000000	Interrupt Status
FSPI_FSR	0x0020	W	0x00000001	FIFO Status Register
FSPI_SR	0x0024	W	0x00000000	FSPI Status Register
FSPI_RISR	0x0028	W	0x00000000	Raw Interrupt Status Register
FSPI_VER	0x002C	W	0x00000009	Version Register
FSPI_QOP	0x0030	W	0x00000000	Quad Line Operation IO Level Pre-set Register
FSPI_EXT_CTRL	0x0034	W	0x00004023	Extend Control Register

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
FSPI_DLL_CTRL0	0x003C	W	0x00000001	Delay Line Control Register for CS0 Device
FSPI_EXT_AX	0x0044	W	0x0000F0FF	Extend Auxiliary Data Control Register
FSPI_SCLK_INATM_CNT	0x0048	W	0xFFFFFFFF	SCLK Inactive Timeout Counter
FSPI_XMMC_WCMD0	0x0050	W	0x00000000	Memory Mapped Control Write Command Register for CS0 Device
FSPI_XMMC_RCMD0	0x0054	W	0x00000000	Memory Mapped Control Read Command Register for CS0 Device
FSPI_XMMC_CTRL	0x0058	W	0x000072E0	Memory Mapped Control Register
FSPI_MODE	0x005C	W	0x00000000	Controller Working Mode Register
FSPI_DEVRGN	0x0060	W	0x00000017	Device Region Size Register
FSPI_DEVSIZE0	0x0064	W	0x00000012	Device Size Register for CS0 Device
FSPI_TME0	0x0068	W	0x00000000	Timeout Enable Control Register for CS0 Device
FSPI_XMMC_RX_WTMRK	0x0070	W	0x00000002	Memory Mapped Mode Receiver FIFO Water Mark Register
FSPI_DMATR	0x0080	W	0x00000000	DMA Trigger Register
FSPI_DMAADDR	0x0084	W	0x00000000	DMA Address Register
FSPI_LEN_CTRL	0x0088	W	0x00000000	Length Control Register
FSPI_LEN_EXT	0x008C	W	0x00000000	Length Extended Register
FSPI_XMMCSR	0x0094	W	0x00000000	Memory Mapped Status Register
FSPI_CMD	0x0100	W	0x00000000	Indirect Command Register
FSPI_ADDR	0x0104	W	0x00000000	Address Register
FSPI_DATA	0x0108	W	0x00000000	Data Register
FSPI_CTRL1	0x0200	W	0x00000000	Control Register for CS1 Device
FSPI_AX1	0x0214	W	0x00000000	FSPI Auxiliary Data Value for CS1 Device
FSPI_ABIT1	0x0218	W	0x00000000	Extend Address Bits for CS1 Device
FSPI_DBG_IO_CTRL	0x022C	W	0x00000000	Debug IO Control
FSPI_DLL_CTRL1	0x023C	W	0x00000001	Delay Line Control Register for CS1 Device
FSPI_XMMC_WCMD1	0x0250	W	0x00000000	Memory Mapped Control Write Command Register for CS1 Device
FSPI_XMMC_RCMD1	0x0254	W	0x00000000	Memory-Mapped Command Control Register for CS1 Device
FSPI_DEVSIZE1	0x0264	W	0x00000012	Device Size Register for CS1 Device
FSPI_TME1	0x0268	W	0x00000000	Timeout Enable Control Register for CS1 Device

28.4.3 Detail Registers Description

FSPI_CTRL0

Address: Operational Base(0xFF488000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:30	RO	0x0	reserved
29	RW	0x0	WP_EN WP# Port Enable 1'b0: Disable 1'b1: Enable. The WP# port will always be drived by QOP[SO123] when QOP[SO123BP] is setted to disable.
28:14	RO	0x0000	reserved
13:12	RW	0x0	DATB Data Line Width 2'b00: 1 bit, x1 mode 2'b01: 2 bits, x2 mode 2'b10: 4 bits, x4 mode 2'b11: Reserved Set this DATB to match the CMD sequence before doing indirect access mode and memory mapped access mode.
11:10	RW	0x0	ADRB Address Line Width 2'b00: 1 bit, x1 mode 2'b01: 2 bits, x2 mode 2'b10: 4 bits, x4 mode 2'b11: Reserved Set this ADRB to match the CMD sequence before doing indirect access mode and memory mapped access mode.
9:8	RW	0x0	CMDB Command Line Width 2'b00: 1 bit, x1 mode 2'b01: 2 bits, x2 mode 2'b10: 4 bits, x4 mode 2'b11: Reserved Set this CMDB to match the CMD sequence before doing indirect access mode and memory mapped access mode.
7:4	RW	0x0	IDLE_CYCLE Idle Cycles When Switching IO from Output to Input 4'h0: Idle hold is disable 4'h1: Hold the SCLK in idle for 2 cycles when switch to shift in ... 4'hf: Hold the SCLK in idle for 16 cycles when switch to shift in To improve the transform IO timing, the application can set this register to hold the SCLK in low state or high state.
3:2	RO	0x0	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
1	RW	0x0	SHIFTPHASE Shift Phase of Data Input in Controller 1'b0: Shift input data at posedge SCLK 1'b1: Shift input data at negedge SCLK The application can select the input data captured by posedge of SCLK when "0" or negedge of SCLK when "1".
0	RW	0x0	SPIM Serial Peripheral Interface Mode 1'b0: Mode 0 1'b1: Mode 3 SPIM is used to control the serial mode (CPOL and CPHA). CPOL indicates clock polarity of Serial master, CPOL=1 for SCLK high while idle, CPOL=0 for SCLK low while not transmitting. CPHA indicates clock phase. The combination of CPOL bit and CPHA bit decides which Serial mode is supported.

FSPI_IMR

Address: Operational Base(0xFF488000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7	RW	0x1	DMAM DMA Finish Interrupt Mask 1'b0: DMA finish interrupt is not masked 1'b1: DMA finish interrupt is masked Only valid in indirect access mode.
6	RW	0x1	NSPIM NSPI Interrupt Mask 1'b0: NSPI interrupt is not masked 1'b1: NSPI interrupt is masked Valid in indirect access mode and memory mapped mode.
5	RW	0x1	AHBM AMBA AHB Error Interrupt Mask 1'b0: AMBA AHB Error interrupt is not masked 1'b1: AMBA AHB Error interrupt is masked Only valid in indirect access mode.
4	RW	0x1	TRANSM Transfer Finish Interrupt Mask 1'b0: Transfer finish interrupt is not masked 1'b1: Transfer finish interrupt is masked Only valid in indirect access mode.
3	RW	0x1	TXEM Transmit FIFO Empty Interrupt Mask 1'b0: Transmit FIFO empty interrupt is not masked 1'b1: Transmit FIFO empty interrupt is masked Only valid in indirect access mode.

Rockchip Confidential

Bit	Attr	Reset Value	Description
2	RW	0x1	TXOM Transmit FIFO Overflow Interrupt Mask 1'b0: Transmit FIFO overflow interrupt is not masked 1'b1: Transmit FIFO overflow interrupt is masked Only valid in indirect access mode.
1	RW	0x1	RXUM Receive FIFO Underflow Interrupt Mask 1'b0: Receive FIFO underflow interrupt is not masked 1'b1: Receive FIFO underflow interrupt is masked Only valid in indirect access mode.
0	RW	0x1	RXFM Receive FIFO Full Interrupt Mask 1'b0: Receive FIFO full interrupt is not masked 1'b1: Receive FIFO full interrupt is masked Only valid in indirect access mode.

FSPI_ICLR

Address: Operational Base(0xFF488000) + offset (0x0008)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7	W1C	0x0	DMAC DMA Finish Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the DMAS
6	W1C	0x0	NSPIC NSPI Error Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the NSPIS.
5	W1C	0x0	AHBC AMBA AHB Error Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the AHBS.
4	W1C	0x0	TRANSC Transfer Finish Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the TRANSS.
3	W1C	0x0	TXEC Transmit FIFO Empty Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the TXES.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
2	W1C	0x0	TXOC Transmit FIFO Overflow Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the TXOS.
1	W1C	0x0	RXUC Receive FIFO Underflow Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the RXUS.
0	W1C	0x0	RXFC Receive FIFO Full Interrupt Clear 1'b0: No action 1'b1: Clear interrupt Write "1" to clear the RXFS.

FSPI_FTLR

Address: Operational Base(0xFF488000) + offset (0x000C)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:8	RW	0x10	RXFTLR Receive FIFO Threshold Level 8'h0: 0 entry level 8'h1: 1 entry level ... 8'h10: 16 entry level(default) ... When the number of receive FIFO entries is bigger than or equal to this value, the receive FIFO full interrupt is triggered.
7:0	RW	0x10	TXFTLR Transmit FIFO Threshold Level 8'h0: 0 entry level 8'h1: 1 entry level ... 8'h10: 16 entry level(default) ... When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.

FSPI_RCVR

Address: Operational Base(0xFF488000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
0	R/WSC	0x0	RCVR FSPI Recover Write any values to trigger the recovery of SMC NSPI state machine, FIFO state and other logic state.

FSPI_AX0

Address: Operational Base(0xFF488000) + offset (0x0014)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x00	AX Auxiliary Data The AX value when doing the continuous read (enhance mode or XIP mode). That is M7-M0 in "Continuous Read Mode".

FSPI_ABIT0

Address: Operational Base(0xFF488000) + offset (0x0018)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4:0	RW	0x00	ABIT Address Bits Extend 5'h0: 1 bit 5'h1: 2 bits ... 5'h1f: 32 bits Only valid when ADDRB is set to 2'b11.

FSPI_ISR

Address: Operational Base(0xFF488000) + offset (0x001C)

Bit	Attr	Reset Value	Description

28.6 Application Notes

28.6.1 Typical Program Flow without DMA

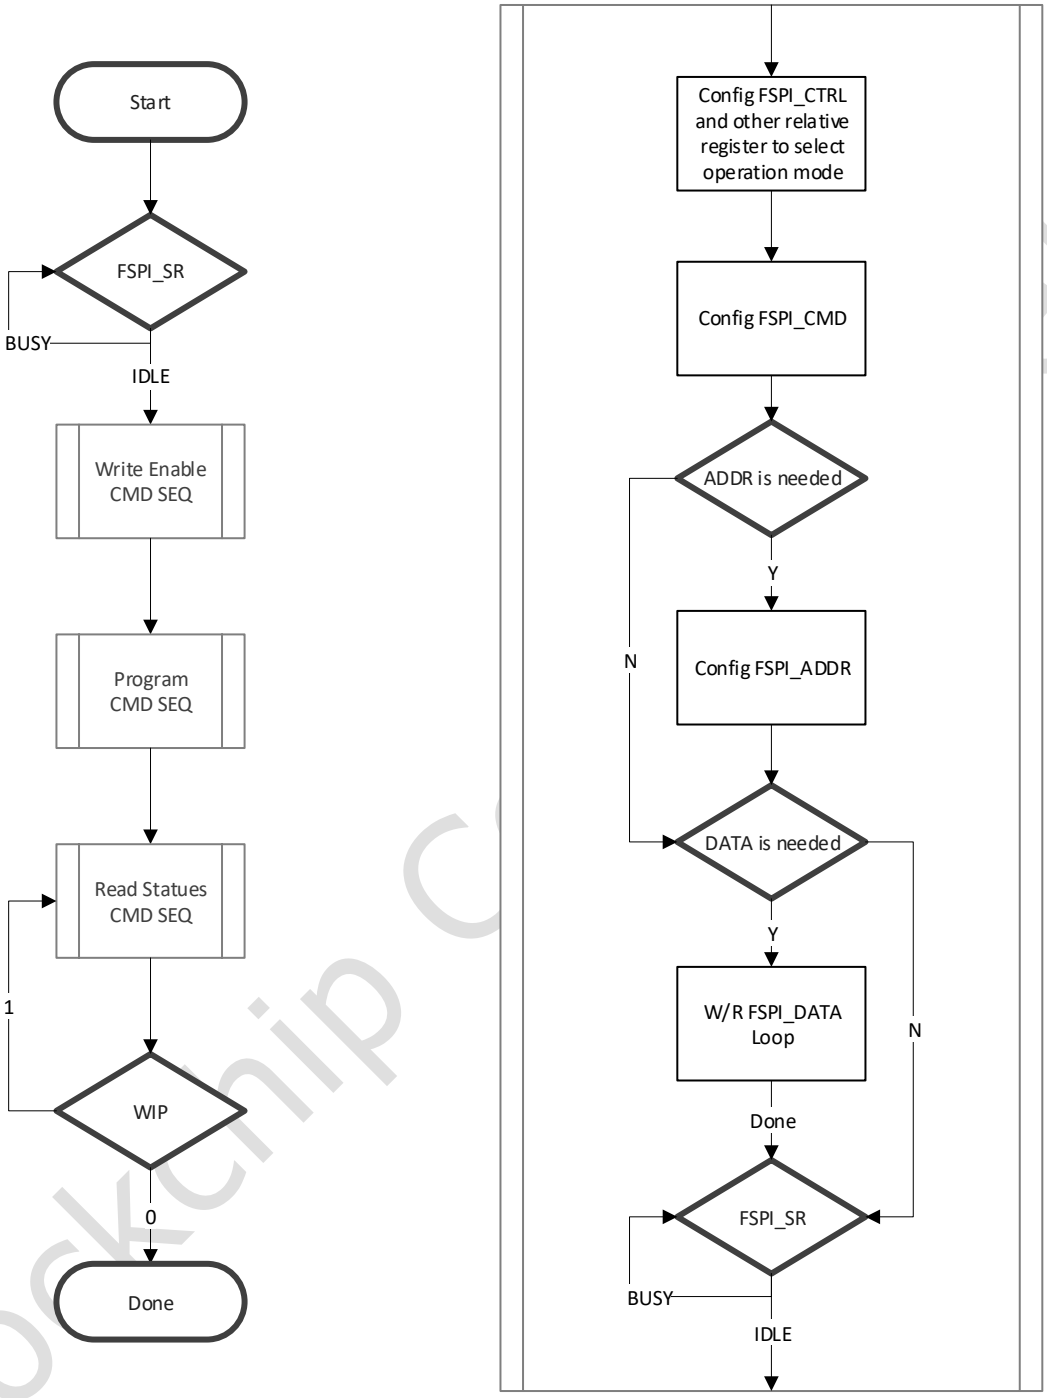

Fig. 28-2 Program Flow

All the AHB bus write data to FSPI_CMD, FSPI_ADDR and FSPI_DATA will be marked with different header and then pushed into transmit FIFO by writing order.

Rockchip C

28.6.2 Typical READ Flow without DMA

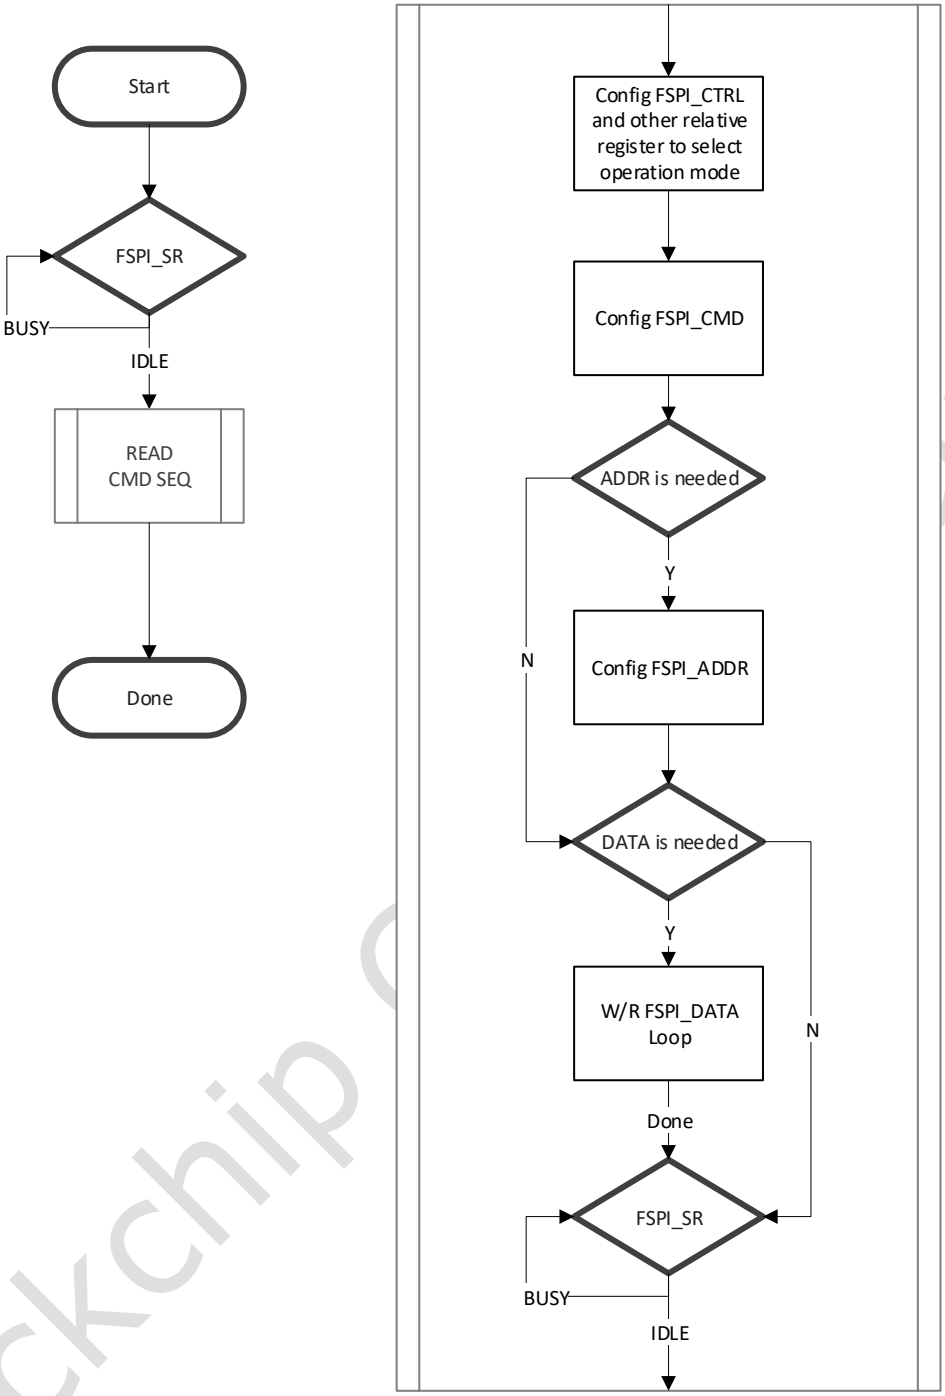

Fig. 28-3 Read Flow

Rockchip Confidential

28.6.3 Command Flow with DMA

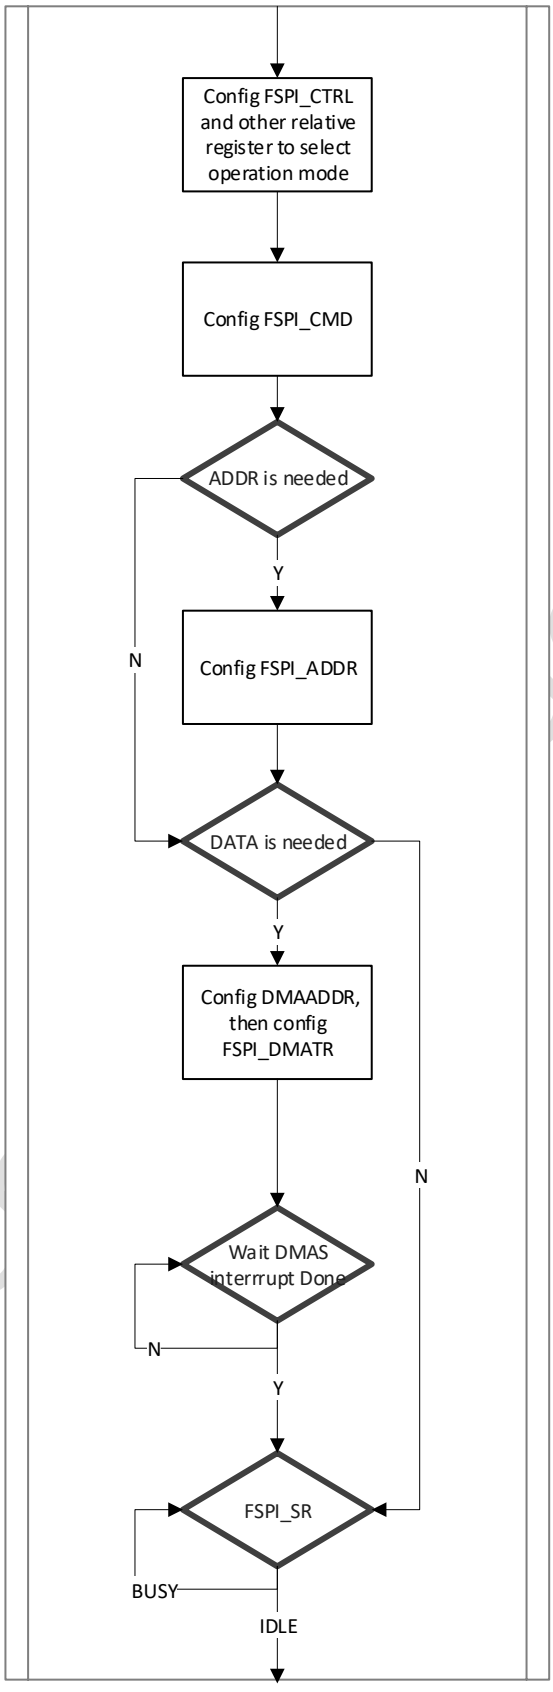

Fig. 28-4 Command with DMA Flow

The total transfer bytes is decided by TRB register in FSPI_CMD and must be aligned to 2 bytes.

28.6.4 SPI Mode and Sampling Phase Control

The register SPIM in FSPI_CTRL will decide the default value of SCLK when CS# is inactive. When SPIM=0, the default value is 0, means Mode 0. When SPIM=1, the default value is 1,

Rockchip Confidential

means SPI Mode 3.

The register SHIFTPAHSE in FSPI_CTRL will decide when to sample the SIO data. If SHIFTPAHSE=0, it will sample the data at the posedge of SCLK sampling clock. If SHIFTPHASE=1, it will sample the data at the negedge of SCLK sampling. The phase delay of sampling clock SCLK is configurable by SMP_DLL_CFG. It is strongly recommended that the SMP_DLL_CFG is set to 1 when SCLK_SMP_SEL is in bypass mode.

Individual FSPI_DLL_CTRL[n] allows flexibly control the DLL for each CSN channel, and the DLL is switched dynamically when the CSN is in operation.

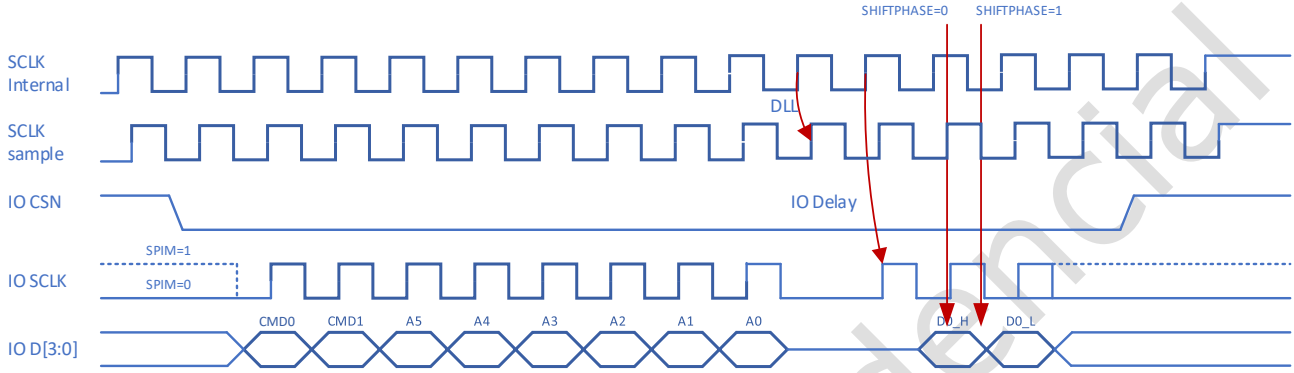

Fig. 28-5 SPI mode

28.6.5 Idle Cycles

The FSPI_CTRL register is a global control register, when the controller is in busy state (FSPI_SR), FSPI_CTRL cannot be set. The field IDLE_CYCLE (FSPI_CTRL[7:4]) of this register are used to configure the idle level cycles of FSPI core clock (SCLK) before reading the first bit of the read command.

Like the following picture shows, the highlighted line of the SCLK is the idle cycles, during these cycles, the chip pad is switched to output. When IDLE_CYCLE =0, it means there will be no idle level cycles.

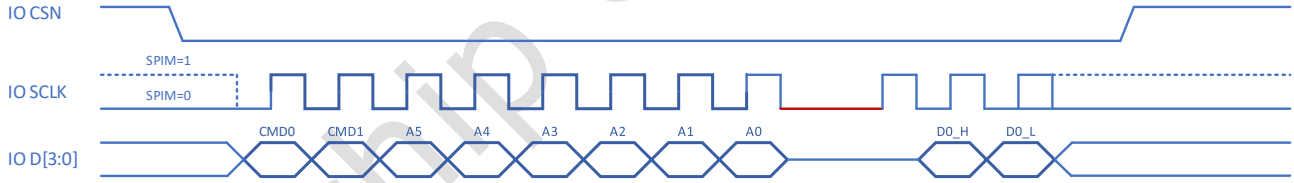

Fig. 28-6 Idle cycles

Rockchip Confidential

Chapter 29 Serial Peripheral Interface (SPI)

29.1 Overview

The Serial Peripheral Interface is an APB slave device. There are four possible combinations for the serial clock phase and polarity. The clock phase (SCPH) determines whether the serial transfer begins with the falling edge of slave select signals or the first edge of the serial clock. The slave select line is held high when the SPI is idle or disabled. This SPI controller can work as either master or slave mode.

SPI Controller supports the following features:

- Support Motorola SPI, TI Synchronous Serial Protocol and National Semiconductor Micro wire interface
- Support 32-bit APB bus
- Support two internal 16-bit wide and 64-location deep FIFOs, one for transmitting and the other for receiving serial data
- Support two chip select signals in master mode
- Support 4,8,16 bit serial data transfer
- Support configurable interrupt polarity
- Support asynchronous APB bus and SPI clock
- Support master and slave mode
- Support DMA handshake interface and configurable DMA water level
- Support transmit FIFO empty, underflow, receive FIFO full, overflow, interrupt and all interrupts can be masked
- Support configurable water level of transmit FIFO empty and receive FIFO full interrupt
- Support combining interrupt output
- Support up to half of SPI clock frequency transfer in master mode and one quarter of SPI clock frequency transfer in slave mode
- Support full and half duplex mode transfer
- Stop transmitting SCLK if transmit FIFO is empty or receive FIFO is full in master mode
- Support configurable delay from chip select active to SCLK active in master mode
- Support configurable period of chip select inactive between two parallel data in master mode
- Support big and little endian, MSB and LSB first transfer
- Support two 8-bit audio data store together in one 16-bit wide location
- Support sample MISO 0~3 SPI clock cycles later at master mode
- Support configurable SCLK polarity and phase
- Support fix and incremental address access to transmit and receive FIFO
- Support timeout mechanism in slave mode
- Support BYPASS slave mode, in which MISO and MOSI logic are driven by SCLK_IN directly instead of spi_clk

29.2 Block Diagram

The SPI Controller comprises with:

- AMBA APB interface and DMA Controller Interface
- Transmit and receive FIFO controllers and an FSM controller
- Register block
- Shift control and interrupt

Rockchip Confidential

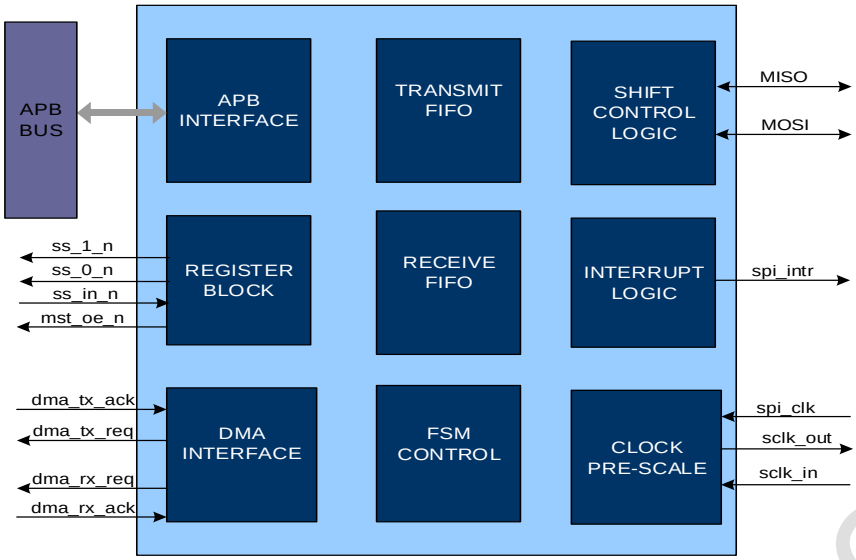

Fig. 29-1 SPI Controller Block Diagram

APB INTERFACE

The host processor accesses data, control, and status information on the SPI through the APB interface. The SPI supports APB data bus widths of 32 bits and 8 or 16 bits when reading or writing internal FIFO if data frame size (SPI_CTRL0[1:0]) is set to 8 bits.

DMA INTERFACE

This block has a handshaking interface to a DMA Controller to request and control transfers. The APB bus is used to perform the data transfer to or from the DMA Controller.

FIFO LOGIC

For transmit and receive transfers, data transmitted from the SPI to the external serial device is written into the transmit FIFO. Data received from the external serial device into the SPI is pushed into the receive FIFO. Both FIFOs are 64x16bits.

FSM CONTROL

Control the state's transformation of the design.

REGISTER BLOCK

All registers in the SPI are addressed at 32-bit boundaries to remain consistent with the APB bus. Where the physical size of any register is less than 32-bits wide, the upper unused bits of the 32-bit boundary are reserved. Writing to these bits has no effect; reading from these bits returns 0.

SHIFT CONTROL

Shift control logic shift the data from the transmit FIFO or to the receive FIFO. This logic automatically right-justifies receive data in the receive FIFO buffer.

INTERRUPT CONTROL

The SPI supports combined and individual interrupt requests, each of which can be masked. The combined interrupt request is the OR relationship between all other SPI interrupts after masking.

Rockchip Confidential

29.3 Function Description

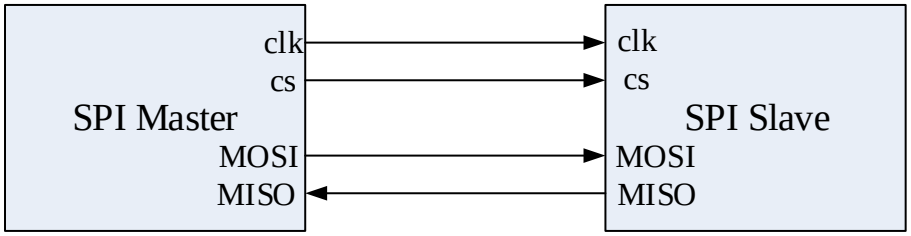

Fig. 29-2 SPI Master and Slave Interconnection

The SPI controller support dynamic switching between master and slave in a system. The diagram shows how the SPI controller connects with other SPI devices.

Operation Modes

The SPI can be configured in the following two fundamental modes of operation: Master Mode when SPI_CTRLR0 [20] is 1'b0, Slave Mode when SPI_CTRLR0 [20] is 1'b1, bypass Slave Mode when SPI_BYPASS[0] is 1'b1, additionally.

Transfer Modes

The SPI operates in the following three modes when transferring data on the serial bus.
1) Transmit and Receive
When SPI_CTRLR0 [19:18] == 2'b00, both transmit and receive logic are valid.
2) Transmit Only
When SPI_CTRLR0 [19:18] == 2'b01, the receive data are invalid and should not be stored in the receive FIFO.
3) Receive Only
When SPI_CTRLR0 [19:18] == 2'b10, the transmit data are invalid.

Clock Ratios

A summary of the frequency ratio restrictions between the bit-rate clock (sclk_out/sclk_in) and the SPI peripheral clock (spi_clk) are described as:
When SPI Controller works as master, the F_{spi_clk}>= 2 × (maximum F_{sclk_out})
When SPI Controller works as normal slave, the F_{spi_clk}>= 4 × (maximum F_{sclk_in})
When SPI Controller works as bypass slave, no frequency ratio restrictions

With the SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. To transmit data, both SPI peripherals must have identical serial clock phase (SCPH) and clock polarity (SCPOL) values. The data frame can be 4/8/16 bits in length.

When the configuration parameter SCPH = 0, data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the MISO and MOSI lines prior to the first serial clock edge. The following two figures show a timing diagram for a single SPI data transfer with SCPH = 0. The serial clock is shown for configuration parameters SCPOL = 0 and SCPOL = 1.

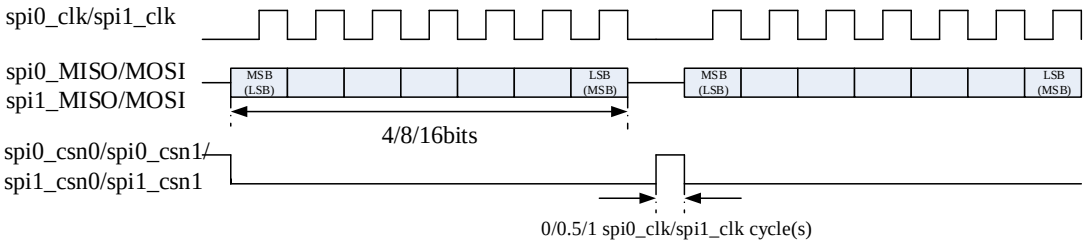

Fig. 29-3 SPI Format (SCPH=0 SCPOL=0)

Rockchip Confidential

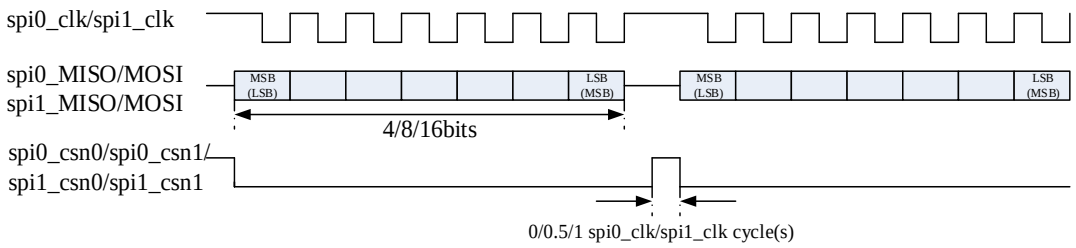

Fig. 29-4 SPI Format (SCPH=0 SCPOL=1)

When the configuration parameter SCPH = 1, both master and slave peripherals begin transmitting data on the first serial clock edge after the slave select line is activated. The first data bit is captured on the second (trailing) serial clock edge. Data are propagated by the master and slave peripherals on the leading edge of the serial clock. During continuous data frame transfers, the slave select line may be held active-low until the last bit of the last frame has been captured. The following two figures show the timing diagram for the SPI format when the configuration parameter SCPH = 1.

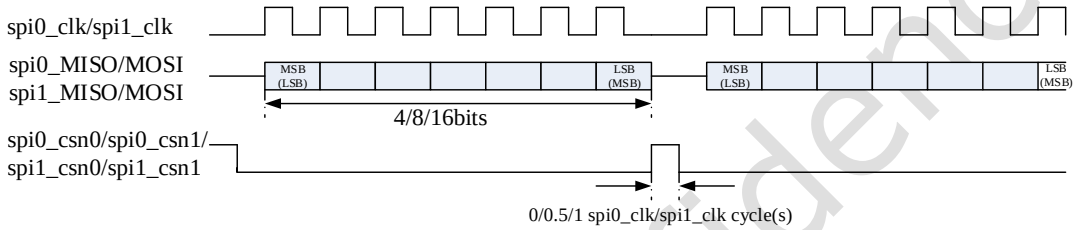

Fig. 29-5 SPI Format (SCPH=1 SCPOL=0)

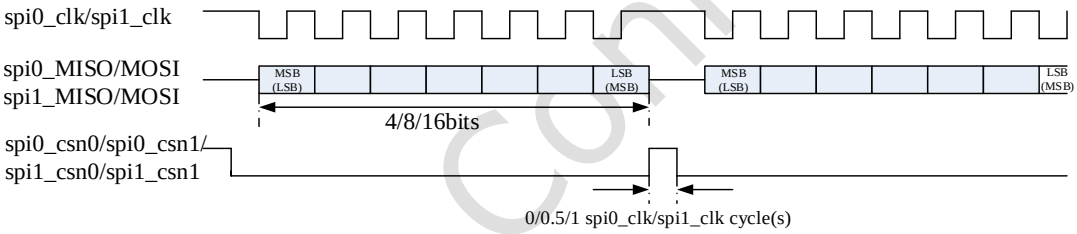

Fig. 29-6 SPI Format (SCPH=1 SCPOL=1)

29.4 Register Description

29.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

SPI_CTRLR1

Address: Operational Base + offset (0x0004)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	ndm When Transfer Mode is receive only, this register field sets the number of data frames to be continuously received by the SPI. The SPI continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 4GB of data in a continuous transfer.

SPI_ENR

Address: Operational Base + offset (0x0008)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	enr Enables and disables all SPI operations. Transmit and receive FIFO buffers are cleared when the device is disabled.

SPI_SER

Address: Operational Base + offset (0x000C)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1:0	RW	0x0	ser Slave enable register. The register enable the individual slave select output lines, 2 slave-select output pins are available. This register is valid only when SPI is configured as a master device.

SPI_BAUDR

Address: Operational Base + offset (0x0010)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	baudr SPI Clock Divider. This register is valid only when the SPI is configured as a master device. The LSB for this field is always set to 0 and is unaffected by a write operation, which ensures an even value is held in this register. If the value is 0, the serial output clock (sclk_out) is disabled. The frequency of the sclk_out is derived from the following equation: Fsclk_out = Fspi_clk/ SCKDV Where SCKDV is any even value between 2 and 65534. For example: for Fspi_clk = 3.6864MHz and SCKDV =2 Fsclk_out = 3.6864/2= 1.8432MHz

SPI_TXFTLR

29.6 Application Notes

Clock Ratios

A summary of the frequency ratio restrictions between the bit-rate clock (sclk_out/sclk_in) and the SPI peripheral clock (spi_clk) are described as:

When SPI Controller works as master, the F_{spi_clk}>= 2 × (maximum F_{sclk_out})

When SPI Controller works as slave, the F_{spi_clk}>= 4 × (maximum F_{sclk_in})

When SPI Controller works as bypass slave, no frequency ratio restrictions

Master Transfer Flow

When configured as a serial-master device, the SPI initiates and controls all serial transfers. The serial bit-rate clock, generated and controlled by the SPI, is driven out on the sclk_out line. When the SPI is disabled (SPI_ENR = 0), no serial transfers can occur and sclk_out is held in "inactive" state, as defined by the serial protocol under which it operates.

Slave Transfer Flow

When the SPI is configured as a slave device, all serial transfers are initiated and controlled by the serial bus master.

When the SPI serial slave is selected during configuration, it enables its transmit data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (sclk_in), driven from the serial-master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge.

Note that when the SPI works at bypass slave mode, since MISO and MOSI are directly driven by sclk_in, data can be received and transmit quickly, and spi_clk can be gated by configuring SPI_BYPASS[3:2].

Chapter 30 SPI2APB

30.1 Overview

SPI2 is an alias for SPI2APB in this system. The SPI2APB module supports the following features:

- External SPI master can access the accessible address space in the chip through SPI2APB convertor
- Support two groups of registers in SGRF to control accessible address space in the chip
- A transaction states register and a message register can be read by external SPI master by query operation
- Two 32 bit registers can be written by external SPI master, and one of them can generate an interrupt after been written. This two register can be read by masters such as CPU and MCU

30.2 Block Diagram

The figure below shows SPI2APB block structure.

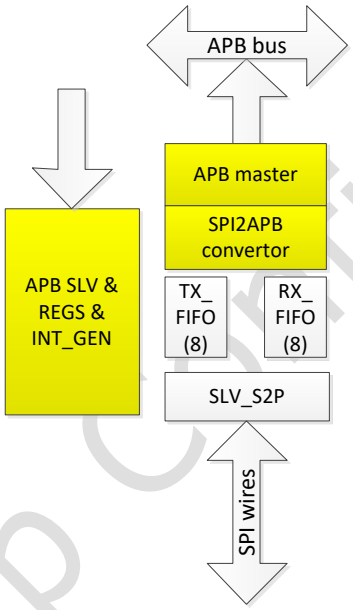

Fig. 30-1 SPI2APB Block Diagram

30.3 Function Description

30.3.1 Overview

SPI2APB convertor receives data from SPI wires, parses the command, and operates according to the protocol.

30.3.2 Protocol Description

SPI2APB supports four types of operation: Write, Read, Query and Write Message. By default, the command, address and data are all transferred in 32 bits packets in little endian, and the first bit to be transferred is the LSB. The operations begin at the negative edge of CS and end at the positive edge of CS. Between two operation, CS should keep high for a time longer than one SCLK period.

Write

External SPI master should dessert CS firstly. The Write command, address and data packets should be transferred according to the order of the figure. The first data (data0 in the Fig. 30-2) will be written to the address ADDR, the second data will be written to the address ADDR+4, and so on. External SPI master can terminate the write operation by setting the CS to high level.

Rockchip Confidencial

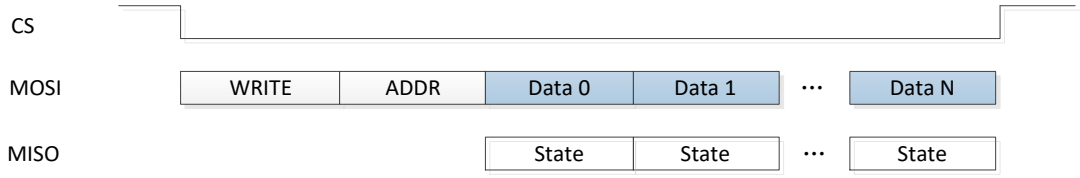

Fig. 30-2 Write Operation

Read

After receiving READ command and address, the convertor will read N data from the address and push the data into the RD_FIFO (N is a parameter in READ command). Dummy packets can be insert to ensure there is available data in the RD_FIFO. When SPI master is ready to receive data, it should send a RD_BEGIN command packet. The first packets following RD_BEGIN packets (data0 in the Fig. 30-3) is the data read from address ADDR, the second packets is the data read from address ADDR+4, and so on. After N data packets has been transferred, SPI2APB will begin to transfer state information.

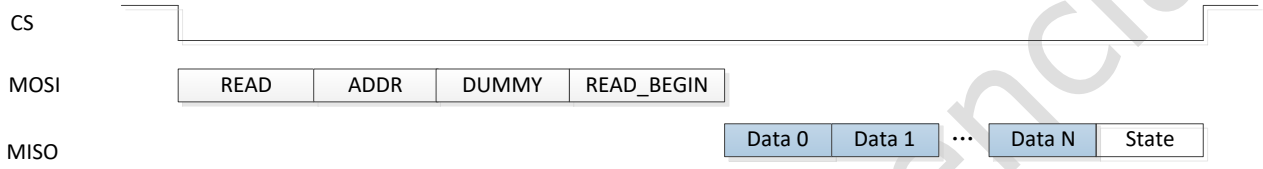

Fig. 30-3 Read Operation

Query

There are two registers can be queried: State Register and Message Register 2. State register contains transfer state information such as whether the transfer is complete or not, detail is showed in the Table 30-1. Message Register 2 can be written by DSP. The query result is immediately following the query command without delay.

Fig. 30-4 Query Operation

Table 30-1 State Register Information

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	RW	0x1608	Chip ID
15:11	RW	0x0	reserved
10	RW	0x0	pre_err Error response is received when APB master is doing pre-read transaction.
9	RW	0x0	rd_udflw Read FIFO is underflow.
8	RW	0x0	rd_err Data with error response has been transmitted.
7:4	RW	0x0	reserved
3	RW	0x0	trans_cfl Transaction conflict. Previous transaction is unfinished and new transaction is launched by SPI master.
2	RW	0x0	trans_unfi Transaction is unfinished.
1	RW	0x0	wr_ovfl Write FIFO is overflow
0	RW	0x0	wr_err Error response is received when APB master is writing

Write Message

There are two message registers can be written by external SPI master: Message Register 0 and Message Register 1. These two registers can be read by DSP. After Message Register 1 has been written, an interrupt will be generated.

The control register (CTRL0) can be written by using this command too.

Fig. 30-5 Write Message Operation

Command Encoding

All command are 32bits.

Table 30-2 Command Encoding Information

Command	Format	Description
READ	0x0077+(PRE_NUM <<16)	PRE_NUM is pre_read number. For example, 0x00100077 indicates pre_read number is 16. If PRE_NUM is 0, convertor will read data when RD_FIFO is not full and read transaction is not terminated.
READ_BEGIN	0x000000aa	Command for read begin.
WRITE	0x00000011	Command for write data.
WRITE MESSAGE (Message Reg0)	0x00010011	Write message register 0.
WRITE MESSAGE (Message Reg1)	0x00020011	Write message register 1 will generate an interrupt.
WRITE MESSAGE (CTRL0)	0x00030011	Write the ctrl0 register.

SPI2APB_QUICK_REG2

Address: **Operational Base** + offset (0x0058)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	QRV CPU write a value to this register, and SPI master read it.

30.5 Interface Description

Table 30-3 SPI0 Interface Description

Module Pin	Dir	Pad Name	IOMUX Setting
IOMUX0			
SPI2_CSN	I/O	GPIO2_B1	GPIO2_IOC_GPIO2B_IOMUX_SEL_0 [7:4]=4'h2
SPI2_CLK	I/O	GPIO2_B0	GPIO2_IOC_GPIO2B_IOMUX_SEL_0 [3:0]=4'h2
SPI2_MOSI	I/O	GPIO2_B2	GPIO2_IOC_GPIO2B_IOMUX_SEL_0 [11:8]=4'h2
SPI2_MISO	I/O	GPIO2_B3	GPIO2_IOC_GPIO2B_IOMUX_SEL_0 [15:12]=4'h2

Notes: I=input, O=output, I/O=input/output.

30.6 Application Notes

1. External SPI master should query the transaction state after every write and read operation to ensure the operation is completed correctly.
2. The frequency of clock for APB should be higher or equal to the frequency of SCLK_IN.

Rockchip Confidential

Chapter 31 Pulse Width Modulation (PWM)

31.1 Overview

The Pulse-Width Modulator (PWM) provides a way to generate a pulse periodic waveform for motor control, it can also act as a digital-to-analog converter with some external components.

The PWM Module supports the following common features:

- Support input capture mode
  - Support measures the high/low polarity effective cycles of input waveform
  - Support generates an interrupt at the transition of input waveform polarity
  - Support a 32-bits high polarity capture counter
  - Support a 32-bits low polarity capture counter
  - Support an input filter to remove glitch
- Support continuous mode and one-shot output mode
  - Support a 32-bits period counter
  - Support a 32-bits duty counter
  - Support configure the polarity in inactive state and duty cycle
  - Support center or left aligned mode
  - Support a 16-bit first dimensional repeat counter and an interrupt for reload operation
  - Support a 16-bit second dimensional repeat counter and an interrupt for one-shot operation
  - Support global synchronization of various channels
- Supports two-stage frequency division of working clock

RK3506 support two PWM controllers, they support some individual feature as following:

- PWM0
  - Support 4 channels
  - Support power key capture mode
  - Support generates waveform through lookup table
- PWM1
  - Support 8 channels
  - Support biphasic counter
  - Support clock frequency meter
  - Support clock counter
  - Support IR transmission in NEC with full repeat, NEC with simple repeat, TC9012 or SONY mode

Rockchip Confidencial

31.2 Block Diagram

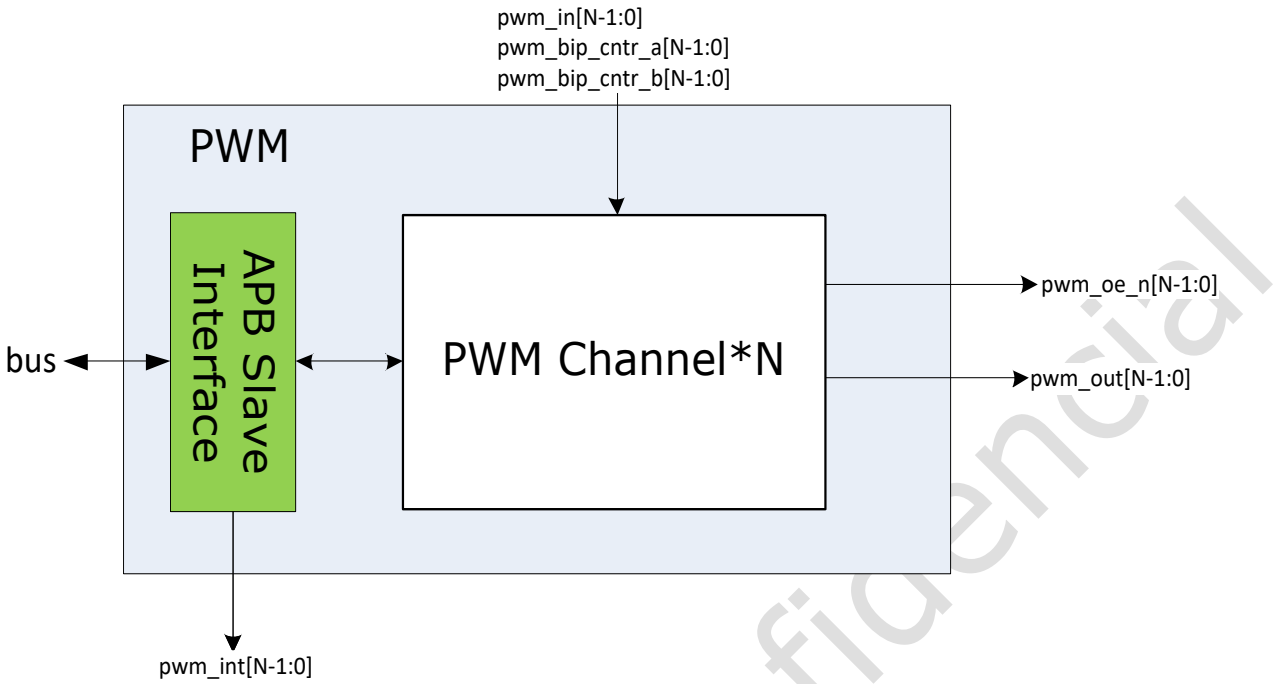

Fig. 31-1 PWM Block Diagram

The host processor gets access to PWM register through the APB slave interface with 32-bit bus width. PWM controller support 1~8 channels, and the offset address of each channel is 4k-byte as interval. PWM supports one interrupt for each channel, user should refer to interrupt register to know the raw interrupt status when an interrupt is asserted.

31.3 Function Description

The PWM supports three operation modes: capture mode, one-shot mode and continuous mode. For the one-shot mode and the continuous mode, the PWM output can be configured as the left-aligned mode or the center-aligned mode.

PWM also supports some additional function, such as clock counter, clock frequency meter and biphasic Counter.

31.3.1 Capture Mode

The capture mode is used to measure the PWM channel input waveform high/low effective cycles with the PWM channel clock and asserts an interrupt when the polarity of the input waveform changes. The number of the high effective cycles is recorded in the PWM_HPC register, while the number of the low effective cycles is recorded in the PWM_LPC register.

Notes: the PWM input waveform is doubled buffered when the PWM channel is working in order to filter unexpected shot-time polarity transition, and therefore the interrupt is asserted several cycles after the input waveform polarity changes, and so does the change of the values of PWM_HPC and PWM_LPC.

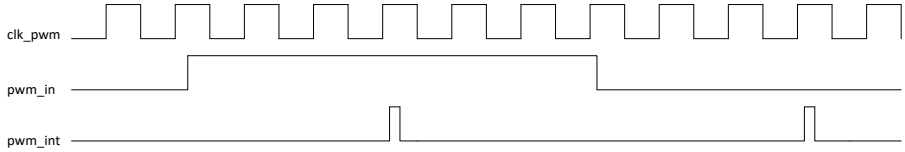

Fig. 31-2 PWM Capture Mode

The PWM supports 32-bits power key capture mode. User can configure 16 power keys to match, the interrupt will be asserted when the capture value matches any one.

31.3.2 Continuous Mode

In continuous mode, the PWM channel generates a series of the pulses continuously as expected once the channel is enabled. It supports left-aligned mode or center-aligned mode.

Rockchip Confidential

For the left-aligned output mode, the PWM channel firstly starts the duty cycle with the configured duty polarity (PWM_CTRL.duty_pol). Once duty cycle number (PWM_DUTY) is reached, the output is switched to the opposite polarity. After the period number (PWM_PERIOD) is reached, the output is again switched to the opposite polarity to start another period of desired pulse.

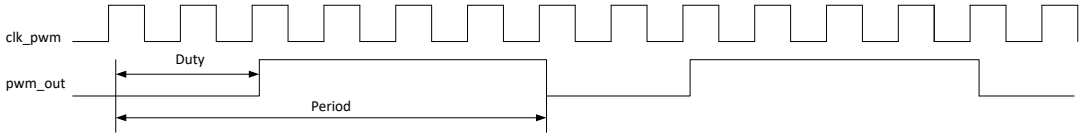

Fig. 31-3 PWM Continuous Left-aligned Output Mode

For the center-aligned output mode, the PWM channel firstly starts the duty cycle with the configured duty polarity (PWM_CTRL.duty_pol). Once one half of duty cycle number (PWM_DUTY) is reached, the output is switched to the opposite polarity. Then if there is one half of duty cycle left for the whole period, the output is again switched to the opposite polarity. Finally, after the period number (PWM_PERIOD) is reached, the output starts another period of desired pulse.

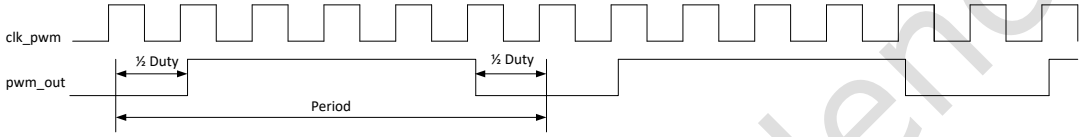

Fig. 31-4 PWM Continuous Center-aligned Output Mode

PWM support a 16 bits first dimensional repeat counter. A reload interrupt is generated every N+1 periods of the waveform when PWM_RPT.rpt_first_dimensional is configured to N. User can update the duty and period configuration for next N+1 periods when receive the interrupt.

PWM also support generates waveform through lookup table, the duty and period can be updated by lookup table automatic every N+1 periods of the waveform.

Continuous mode will generate the waveform continuously until disabled by user. It's will fix to inactive polarity (PWM_CTRL.inactive_pol) when it's disabled.

31.3.3 One-shot Mode

In one-shot mode, the PWM channel generates limited periods of waveforms.

In addition to the first dimensional repeat counter, it also supports a 16 bits second dimensional repeat counter. PWM channel will stop and assert an interrupt after second dimensional counter reach M+1 when PWM_RPT.rpt_second_dimensional is configured to M. The total waveform periods are (N + 1) multi by (M + 1).

The reload interrupt and lookup table is also supported in one-shot mode.

The left-aligned and the center-aligned is also supported in one-shot mode.

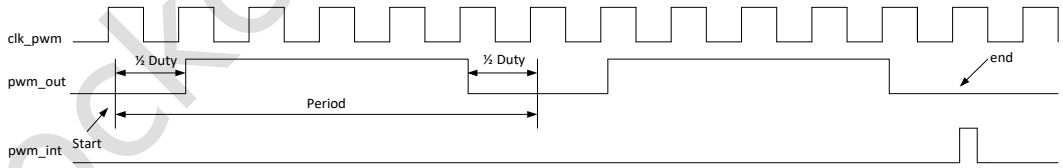

Fig. 31-5 PWM One-shot Center-aligned Output Mode

31.3.4 Clock Counter

PWM support a 64-bits counter which clock can select from any PWM channel input and a clock from system CRU.

31.3.5 Clock Frequency Meter

PWM support a 32-bits frequency meter which clock can select from any PWM channel input and a clock from system CRU. It supports a reference clock and timer to schedule a period time, user can calculate the frequency by getting the counter value that counted by the measured clock in the period time.

31.3.6 Biphasic Counter

PWM supports biphasic counter which uses two IO to compose an A/B phase channel.

PWM1 controller support 7 channel biphasic counters.

For channel 0~channel5, the A phase is from PWM1_BIP_CNTR_A0~A5 (RM_IO), the B

Rockchip Confidential

phase is from PWM1_BIP_CNTR_B0~B5 (RM_IO).
For channel 6, the A phase is from PWM1_CH6 (RM_IO), the B phase is from PWM1_CH7 (RM_IO). The biphasic counter register is only located at PWM1_CH6. User only needs to configure the IOMUX of PWM1_CH7.
Biphasic counter support 5 modes as following:

- Mode 0: Single phase increase mode with A-phase.

When A-phase input is OFF->ON, the count increases by 1. In this mode, it can be used as clock frequency meter or clock counter.

- Mode 1: Single phase increase/decrease mode with A-phase.

When the B-phase input is OFF and the A-phase input is OFF->ON, the count increases by 1.
When the B-phase input is ON and the A-phase input is OFF->ON, the count decreases by 1.

- Mode 2: Dual phase with A/B-phase mode.

When the A-phase input is ON and the B-phase input is OFF->ON, the count increases by 1.
When the A-phase input is ON and the B-phase input is ON->OFF, the count decreases by 1.

- Mode 3: Dual phase with A/B-phase 2 times frequency mode.

When the A-phase input is ON and the B-phase input is OFF->ON, the count increases by 1.
When the A-phase input is OFF and the B-phase input is ON->OFF, the count increases by 1.
When the A-phase input is ON and the B-phase input is ON->OFF, the count decreases by 1.
When the A-phase input is OFF and the B-phase input is OFF ->ON, the count decreases by 1.

- Mode 4: Dual phase with A/B-phase 4 times frequency mode.

When the input of phase B is OFF and phase A is OFF->ON, the count increases by 1.
When the A-phase input is ON and the B-phase input is OFF->ON, the count increases by 1.
When the input of phase B is ON and phase A is ON->OFF, the count increases by 1.
When the A-phase input is OFF and the B-phase input is ON_.OFF, the count increases by 1.
When the A-phase input is OFF and the B-phase input is OFF->ON, the count decreases by 1.
When the input of phase B is ON and phase A is OFF->ON, the count decreases by 1.
When the A-phase input is ON and the B-phase input is ON->OFF, the count decreases by 1.
When the input of phase B is OFF and the input of phase A is ON->OFF, the count decreases by 1.

31.4 Register Description

31.4.1 Internal Address Mapping

Slave address can be divided into different length for different controller, which is shown as follows.

Operational Base

Name	Base Address
PWM0	0xFF930000
PWM1	0xFF170000

Slave address can be divided into different length for different channels in one controller, which is shown as follows.

Table 31-1 PWM Channel Address Map

Channel	Offset Address
Channel 0	0x0000

Rockchip Confidencial

Channel 1	0x1000
Channel 2	0x2000
Channel 3	0x3000
Channel 4	0x4000
Channel 5	0x5000
Channel 6	0x6000
Channel 7	0x7000

7:4	RO	0x4	channel_index Channel index
3:0	RO	0x4	channel_num_support Channel number support

PWM_ENABLE

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:6	RO	0x000	reserved
5	RW	0x0	pwm_cnt_rd_en PWM channel CNT read enable. The CNT can be read for debug. 1'b0: Disabled 1'b1: Enabled
4	W1T	0x0	pwm_global_join_en PWM join global control enable. When this bit is set to 1, the PWM channel is enabled by pwm_global_en instead of pwm_en, and the following register can be updated at the posedge of pwm_global_ctrl_update_en: PWM_CTRL, PWM_PERIOD, PWM_DUTY, PWM_OFFSET

Rockchip Confidencial

Bit	Attr	Reset Value	Description
3	RW	0x0	force_clk_en 1'b0: Disabled, when PWM channel is inactive state, the clk_pwm to PWM Clock pre-scale module is blocked to reduce power consumption. 1'b1: Enabled, the clk_pwm to PWM Clock pre-scale module is always enabled.
2	W1T	0x0	pwm_ctrl_update_en PWM control update enable. The bit will be auto cleaned. The following register can be updated at the posedge of pwm_ctrl_update_en: PWM_CTRL, PWM_PERIOD, PWM_DUTY, PWM_OFFSET
1	RW	0x0	pwm_en PWM enable 1'b0: Disabled 1'b1: Enabled If the PWM is worked in the one-shot mode, this bit will be cleared at the end of operation.
0	RW	0x0	pwm_clk_en PWM clock enable 1'b0: Disabled 1'b1: Enabled If the PWM is worked in the one-shot mode, this bit will be cleared at the end of operation.

PWM_CLK_CTRL

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15	RW	0x0	clk_global_sel Clock global selection 1'b0: Select current channel scale clock 1'b1: Select global channel scale clock
14:13	RW	0x0	clk_src_sel Clock source selection 2'b00: Select clk_pwm as root clock source, Clock is from PLL and the frequency can be configured. 2'b01: Select clk_pwm_osc as root clock source, Clock is from crystal oscillator and the frequency is fixed. 2'b10: Select clk_pwm_rc as root clock source, Clock is from RC oscillator and the frequency is fixed.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
12:4	RW	0x000	scale This field defines the scale factor applied to pre-scaled clock. The value N means the clock is divided by 2*N. it is valid from 1~256.
3	RO	0x0	reserved
2:0	RW	0x0	prescale This field defines the pre-scale factor applied to input clock. The value N means that the input clock is divided by 2^N.

PWM_CTRL

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:9	RO	0x00	reserved
8:6	RW	0x0	pwm_in_sel PWM in channel selection, the default value is corresponding channel, User can configure to another channel. 3'b000: PWM channel 0 3'b001: PWM channel 1 3'b010: PWM channel 2 3'b011: PWM channel 3 3'b100: PWM channel 4 3'b101: PWM channel 5 3'b110: PWM channel 6 3'b111: PWM channel 7
5	RW	0x0	aligned_vld_n 0: Aligned Mode Valid 1: Aligned Mode Invalid
4	RW	0x0	output_mode 1'b0: Left aligned mode 1'b1: Center aligned mode
3	RW	0x0	inactive_pol This defines the output waveform polarity when PWM channel is in inactive state. The inactive state means that PWM finishes the complete waveform in one-shot mode or PWM channel is disabled. 1'b0: Negative 1'b1: Positive

Rockchip Confidencial

Bit	Attr	Reset Value	Description
2	RW	0x0	duty_pol This defines the polarity for duty cycle. PWM starts the output waveform with duty cycle. 1'b0: Negative 1'b1: Positive
1:0	RW	0x0	pwm_mode 2'b00: One shot mode, PWM produces the waveform within the repeated times defined by PWMx_CTRL_rpt. 2'b01: Continuous mode, PWM produces the waveform continuously. 2'b10: Capture mode, PWM measures the cycles of high/low polarity of input waveform. 2'b11: Reserved

PWM_PERIOD

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	PERIOD This value defines the period of the output waveform for continuous mode or one-shot mode. Note that, if the PWM is operated at the center-aligned mode, the period should be an even one, and therefore only the bit [31:1] is considered and bit [0] always considered as 0.

PWM_DUTY

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	DUTY This value defines the duty cycle of the output waveform for continuous mode or one-shot mode. The PWM starts the output waveform with duty cycle. Note that, if the PWM is operated at the center-aligned mode, the period should be an even one, and therefore only the [31:1] is considered.

PWM_OFFSET

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	channel_output_offset If PWM is operated at the continuous mode or one-shot mode, this value defines the offset of the output waveform. This value is based on the PWM clock. The value ranges from 0 to (period-duty). This register takes effective when output aligned mode is invalid.

PWM_RPT

Rockchip Confidencial

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	rpt_second_dimensional This field defines the second dimensional repeated effective periods of output waveform. It can be used only in one-shot mode. The second dimensional waveform counter will increase 1 when first dimensional waveform counter reach rpt_first_dimensional. When reach rpt_second_dimensional, the PWM channel will be disabled and the one-shot interrupt will be asserted. The value N means N+1 repeated effective periods. The total waveform number will be (rpt_first_dimensional+1) multiply by (rpt_second_dimensional+1).
15:0	RW	0x0000	rpt_first_dimensional This field defines the first dimensional repeated effective periods of output waveform. When reach rpt_first_dimensional, the waveform counter will wrap back to 0 and restart counting and the reload interrupt will be asserted. User can update the configuration in the interrupt. It can be used in one-shot mode and Continuous mode. The value N means N+1 repeated effective periods.

PWM_FILTER_CTRL

Address: **Operational Base** + offset (0x0020)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:10	RO	0x00	reserved
9:4	RW	0x00	filter_number Filter window number
3:1	RO	0x0	reserved
0	RW	0x0	filter_enable 1'b0: Disabled 1'b1: Enabled

PWM_CNT

Address: **Operational Base** + offset (0x0024)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	CNT The 32-bit indicates current value of PWM Channel 0 counter. The counter runs at the rate of PWM clock. The value ranges from 0 to (2^32-1).

PWM_ENABLE_DELAY

Rockchip Confidential

Address: **Operational Base** + offset (0x0028)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	pwm_enable_delay PWM enable delay

PWM_HPC

Address: **Operational Base** + offset (0x002C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	HPC This value indicates the effective high polarity cycles of input waveform for capture mode. This value is based on the PWM clock. The value ranges from 0 to (2^32-1).

PWM_LPC

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	LPC This value indicates the effective low polarity cycles of input waveform for capture mode. This value is based on the PWM clock. The value ranges from 0 to (2^32-1).

PWM_BIPHASIC_COUNTER_CTRL0

Address: **Operational Base** + offset (0x0040)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:10	RO	0x00	reserved
9	RW	0x0	biphasic_counter_mode0_edge_sel biphasic counter phase edge selection for mode 0 1'b0: Posedge 1'b1: Negedge
8	RW	0x0	biphasic_counter_clk_force_en Biphasic counter clock force enable
7	W1T	0x0	biphasic_counter_sync_en Biphasic counter synchronous enable

Rockchip Confidencial

Bit	Attr	Reset Value	Description
6	W1T	0x0	timer_clk_switch_mode Timer clock switch mode, it can set to 1'b1 only when biphasic_counter_mode is mode0. 1'b0: Normal mode 1'b1: Switch timer clock and measured clock. It can be used to provide testing accuracy or reduce testing time when the frequency of measured clock is low. It can also be used in scenarios where the start time of the measured clock is uncertain
5:3	RW	0x0	biphasic_counter_mode Biphasic counter mode 3'h0: Mode0 3'h1: Mode1 3'h2: Mode2 3'h3: Mode3 3'h4: Mode4 Other: Reserved
2	RW	0x0	biphasic_counter_clk_sel Biphasic counter clock selection 1'b0: Select clk_pwm, clock is from PLL and the frequency can be configured. 1'b1: Select clk_pwm_osc, clock is from crystal oscillator and the frequency is fixed.
1	RW	0x0	biphasic_counter_continuous_mode Biphasic counter continuous mode
0	W1T	0x0	biphasic_counter_en Biphasic counter enable.

PWM_BIPHASIC_COUNTER_CTRL1

Address: **Operational Base** + offset (0x0044)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:11	RO	0x00	reserved
10:4	RW	0x00	biphasic_counter_filter_number Filter window number
3:1	RO	0x0	reserved
0	RW	0x0	biphasic_counter_filter_enable 1'b0: Disabled 1'b1: Enabled

PWM_BIPHASIC_COUNTER_TIMER_VALUE

Address: **Operational Base** + offset (0x0048)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	biphasic_counter_timer_value Biphasic counter timer value, the unit is one cycle of biphasic counter timer clock.

PWM_BIPHASIC_COUNTER_RESULT_VALUE

Address: **Operational Base** + offset (0x004C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	biphasic_counte_result_value Biphasic counter result value, it can read only after interrupt biphasic_counter_intsts is asserted.

PWM_BIPHASIC_COUNTER_RESULT_VALUE_SYNC

Address: **Operational Base** + offset (0x0050)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	biphasic_counte_result_value_sync Biphasic counter result value with synchronized processing, it can read in real time when biphasic_counter_sync_en is set to 1.

PWM_INTSTS

Address: **Operational Base** + offset (0x0070)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9	W1C	0x0	biphasic_counter_intsts Biphasic counter interrupt status 1'b0: Interrupt not generated 1'b1: Interrupt generated
8	W1C	0x0	wave_middle_intsts Waveform address access middle address value interrupt status 1'b0: Interrupt not generated 1'b1: Interrupt generated

0	RW	0x0	cap_lpc_int_mask LPC interrupt mask for capture mode 1'b0: Interrupt not mask 1'b1: Interrupt mask

PWM_WAVE_MEM_ARBITER

Address: **Operational Base** + offset (0x0080)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	wave_mem_read_lock Each bit controls the read lock of waveform generator memory. Once one channel obtains arbitration, other channels cannot read waveform generator memory. 1'b0: Don't lock 1'b1: Lock
15:8	RO	0x00	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
7:0	RW	0x00	wave_mem_grant Each bit controls the grant of waveform generator memory for one channel. Once one channel obtains arbitration, other channels cannot write waveform generator memory. 1'b0: Don't Grant 1'b1: Grant

PWM_WAVE_MEM_STATUS

Address: **Operational Base** + offset (0x0084)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RO	0x0	access_done Indicate the access to waveform generator memory is done.

PWM_WAVE_CTRL

Address: **Operational Base** + offset (0x0088)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:11	RW	0x00	wave_period_amplify Waveform generator table period value amplify, the value N means amplify by 2^N.
10:6	RW	0x00	wave_duty_amplify Waveform generator table duty value amplify, the value N means amplify by 2^N.
5:4	RW	0x1	wave_mem_clk_sel Waveform generator memory clock selection 2'b00: Select clk_pwm 2'b01: Select clk_pwm_osc 2'b10: Select clk_pwm_rc
3	RW	0x0	wave_update_mode Waveform generator update mode 1'b0: The address will wrap back to minimum address when increase to maximum address, and then increase again. 1'b1: The address will change to decreasing when increasing to the maximum address. it will return to increasing when decrease to the minimum value.
2	RW	0x0	wave_width_mode Waveform generator width mode 1'b0: 8bits 1'b1: 16bits Note: The table is 8bit, User can compose 16 bits with two adjacent addresses

Rockchip Confidential

Bit	Attr	Reset Value	Description
1	RW	0x0	wave_period_en Waveform generator period enable. The period cycle of the output waveform is controlled by waveform generator table instead of register PWM_PERIOD when this bit is set to 1. The period will be updated every waveform number of rpt_first_dimensional.
0	RW	0x0	wave_duty_en Waveform generator duty enable. The duty cycle of the output waveform is controlled by waveform generator table instead of register PWM_DUTY when this bit is set to 1. The duty will be updated every waveform number of rpt_first_dimensional.

PWM_WAVE_MAX

Address: **Operational Base** + offset (0x008C)

Bit	Attr	Reset Value	Description
31:26	RO	0x00	reserved
25:16	RW	0x000	wave_period_max The maximum index of period.
15:10	RO	0x00	reserved
9:0	RW	0x000	wave_duty_max The maximum index of duty.

PWM_WAVE_MIN

Address: **Operational Base** + offset (0x0090)

Bit	Attr	Reset Value	Description
31:26	RO	0x00	reserved
25:16	RW	0x000	wave_period_min The minimum index of period.
15:10	RO	0x00	reserved
9:0	RW	0x000	wave_duty_min The minimum index of duty.

PWM_WAVE_OFFSET

Address: **Operational Base** + offset (0x0094)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RW	0x000	wave_offset The initial offset index of duty and period

PWM_WAVE_MIDDLE

Address: **Operational Base** + offset (0x0098)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RW	0x000	wave_middle The middle index of duty and period.

Rockchip Confidential

PWM_WAVE_HOLD

Address: **Operational Base** + offset (0x009C)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	middle_hold The time to hold at middle index. the unit is waveform number of rpt_first_dimensional
15:8	RW	0x00	min_hold The time to hold at minimum index. the unit is waveform number of rpt_first_dimensional
7:0	RW	0x00	max_hold The time to hold at maximum index. the unit is waveform number of rpt_first_dimensional

PWM_GLOBAL_ARBITER

Address: **Operational Base** + offset (0x00C0)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	global_read_lock Each bit controls the read lock of global control registers. Once one channel obtains arbitration, other channels cannot read global registers. 1'b0: Don't lock 1'b1: Lock
15:8	RO	0x00	reserved
7:0	RW	0x00	global_grant Each bit controls the grant of global control for one channel. Once one channel obtains arbitration, other channels cannot write global registers. 1'b0: Don't Grant 1'b1: Grant

PWM_GLOBAL_CTRL

Address: **Operational Base** + offset (0x00C4)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:2	RO	0x0000	reserved
1	W1T	0x0	global_pwm_ctrl_update_en PWM global control update enable. The bit will be auto cleaned. The following register can be updated at the posedge of pwm_ctrl_update_en: PWM_CTRL, PWM_PERIOD, PWM_DUTY, PWM_OFFSET

Rockchip Confidential

Bit	Attr	Reset Value	Description
0	RW	0x0	global_pwm_en Global PWM enable 1'b0: Disabled 1'b1: Enabled If the PWM is worked in the one-shot mode, this bit will be cleared at the end of operation.

PWM_PWRMATCH_ARBITER

Address: **Operational Base** + offset (0x0100)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	pwrkey_read_lock Each bit controls the read lock of power key function. Once one channel obtains arbitration, other channels cannot read power key registers. 1'b0: Don't lock 1'b1: Lock
15:8	RO	0x00	reserved
7:0	RW	0x00	pwrkey_grant Each bit controls the grant of power key function for one channel. Once one channel obtains arbitration, other channels cannot write power key registers. 1'b0: Don't Grant 1'b1: Grant

PWM_PWRMATCH_CTRL

Address: **Operational Base** + offset (0x0104)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:4	RO	0x000	reserved
3	RW	0x0	pwrkey_int_ctrl 1'b0: Assert interrupt after key capture with power key match 1'b1: Assert interrupt after key capture without power key match
2	RW	0x0	pwrkey_capture_ctrl 1'b0: Capture the value after interrupt 1'b1: Capture the value directly
1	RW	0x0	pwrkey_polarity 1'b0: PWM in polarity is positive 1'b1: PWM in polarity is negative
0	RW	0x0	pwrkey_enable 1'b0: Disabled 1'b1: Enabled

Bit	Attr	Reset Value	Description
3	RW	0x0	it_trans_mode 1'b0: One shot mode, PWM produces the waveform within the repeated times defined by ir_trans_rtp_cnt. 1'b1: Continuous mode, PWM produces the waveform continuously.
2	RW	0x0	it_trans_inactive_pol This defines the output waveform polarity when PWM channel is in inactive state. The inactive state means that PWM finishes the complete waveform in one-shot mode or PWM channel is disabled. 1'b0: Negative 1'b1: Positive
1	RW	0x0	ir_trans_duty_pol This defines the polarity for duty cycle. PWM starts the output waveform with duty cycle. 1'b0: Negative 1'b1: Positive
0	RW	0x0	ir_trans_out_enable 1'b0: disable PWM IR Trans Out Function 1'b1: enable PWM IR Trans Out Function

PWM_IR_TRANS_CTRL1

Address: **Operational Base** + offset (0x0188)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	ir_trans_rpt This field defines the repeated number for IR transmission. The value N means N+1 repeated effective periods.

PWM_IR_TRANS_PRE

Address: **Operational Base** + offset (0x018C)

Bit	Attr	Reset Value	Description
31:16	RW	0x1194	ir_trans_out_high_preload IR Trans Out High Preload Register
15:0	RW	0x2328	ir_trans_out_low_preload IR Trans Out Low Preload Register

PWM_IR_TRANS_SPRE

Address: **Operational Base** + offset (0x0190)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description

0	W1T	0x0	freq_en Frequency Meter enable.

PWM_FREQ_TIMER_VALUE

Address: **Operational Base** + offset (0x01C8)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	freq_timer_value Frequency Meter timer value, the unit is one cycle frequency meter timer clock.

PWM_FREQ_RESULT_VALUE

Address: **Operational Base** + offset (0x01CC)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	freq_result_value The frequency result value, the unit is one cycle of tested clock. Once the freq_intsts interrupt is asserted, User can get the frequency by this value. When timer_clk_switch_mode set to 1'b0, the frequency result is (freq_timer*freq_result_value)/freq_timer_value. When timer_clk_switch_mode set to 1'b1, the frequency result is (freq_timer*freq_timer_value)/freq_result_value. Notes: freq_osc is the frequency of SOC crystal oscillator.

PWM_COUNTER_ARBITER

Address: **Operational Base** + offset (0x0200)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	counter_read_lock Each bit controls the read lock of counter function. Once one channel obtains arbitration, other channels cannot read counter registers. 1'b0: Don't lock 1'b1: Lock
15:8	RO	0x00	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
7:0	RW	0x00	counter_grant Each bit controls the grant of counter for one channel. Once one channel obtains arbitration, other channels cannot write counter registers. 1'b0: Don't Grant 1'b1: Grant

PWM_COUNTER_CTRL

Address: **Operational Base** + offset (0x0204)

Bit	Attr	Reset Value	Description
31:16	WO	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:7	RO	0x000	reserved
6	W1T	0x0	counter_clr Counter value clear.
5:3	RW	0x0	counter_channel_sel Counter channel selection. It's valid only when counter_clk_sel set to 1'b00. 3'b000: PWM channel 0 3'b001: PWM channel 1 3'b010: PWM channel 2 3'b011: PWM channel 3 3'b100: PWM channel 4 3'b101: PWM channel 5 3'b110: PWM channel 6 3'b111: PWM channel 7
2:1	RW	0x0	counter_clk_sel Counter clock selection 1'b0: Input from PWM IO 1'b1: Counter clock from CRU
0	RW	0x0	counter_en Counter enable.

PWM_COUNTER_LOW

Address: **Operational Base** + offset (0x0208)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	counter_low_bits Indicates low 32bits of counter value. The value of counter ranges from 0 to 2^64-1, The unit is one cycle of tested clock

PWM_COUNTER_HIGH

Address: **Operational Base** + offset (0x020C)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	counter_high_bits Indicates high 32bits of the counter value. The value of counter ranges from 0 to 2^64-1, The unit is one cycle of tested clock

PWM_WAVE_MEM

31.5 Interface Description

Table 31-2 PWM Rockchip Matrix IO Interface Description

Module Pin	Direction	Rockchip Matrix IO	IOMUX Setting
PWM0_CH0~CH3	I/O	RM_IO	
PWM1_CH0~CH7	I/O	RM_IO	
PWM1_BIP_CNTR_A0~A5	I	RM_IO	
PWM1_BIP_CNTR_B0~B5	I	RM_IO	

Notes: I=input, O=output, I/O=input/output. For the configuration of RM_IO, please refer to chapter "Rockchip Matrix IO".

31.6 Application Notes

31.6.1 PWM Capture Mode Standard Usage Flow

1. Set PWM_ENABLE.pwm_en to 1'b0 to disable the PWM channel.
2. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel to configure the clock selection and division.
3. Set PWM_CTRL.pwm_mode to 2'b10 to select capture mode.
4. Set PWM_INT_EN.cap_lpc_int_en/cap_hpc_int_en to 1'b1 to enable the interrupt.
5. Set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b1 to enable the channel.
6. When an interrupt is asserted, refer to PWM_INTSTS register to know the raw interrupt status. User should read the PWM_HPC register to know the effective high cycles of input waveforms when cap_hpc_intsts is asserted and read the PWM_LPC register to know the effective low cycles when cap_lpc_intsts is asserted. User should set 1'b1 to correspond bit of PWM_INTSTS to clear the interrupt.
7. If user want to disable PWM channel, set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b0.

31.6.2 PWM Power Key Capture Mode Standard Usage Flow

1. Set PWM_ENABLE.pwm_en to 1'b0 to disable the PWM channel.
2. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel to configure the clock selection and division. The clock frequency should be 1 MHz after division.
3. Set PWM_CTRL.pwm_mode to 2'b10 to select capture mode.
4. Set PWM_PWRMATCH_ARBITER.pwrkey_grant to 8'b01 to set channel 0 for capture.
5. Set PWM_INT_EN.pwr_int_en to 1'b1 to enable the interrupt.
6. Set PWM_PWRMATCH_VALUE0~15 registers for the 16 power key match value.
7. Set max_cnt and min_cnt of follow register: PWM_PWRMATCH_LPRE, PWM_PWRMATCH_HPRE, PWM_PWRMATCH_LD, PWM_PWRMATCH_HD_ZERO, PWM_PWRMATCH_HD_ONE. It doesn't need to set these registers if the default value can meet the requirement.

Rockchip Confidential

8. Set PWM_PWRMATCH_CTRL.pwrkey_polarity for the polarity of power key signal.
9. Set PWM_PWRMATCH_CTRL.pwrkey_enable to 1'b1 to enable power key mode.
10. Set PWM_FILTER_CTRL.filter_number/filter_enable to enable filter. (Optional).
11. Set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b1 to enable the channel.
12. When an interrupt is asserted, refer to PWM_INTSTS register to know the raw interrupt status, and refer to PWM_PWRCAPTURE_VALUE to know the power key capture value. User should set 1'b1 to correspond bit of PWM_INTSTS to clear the interrupt.
13. If user want to disable PWM channel, set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b0.

31.6.3 PWM Continuous Standard Usage Flow

1. Set PWM_ENABLE.pwm_en to 1'b0 to disable the PWM channel.
2. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel to configure the clock selection and division.
3. Set PWM_CTRL.output_mode/duty_pol/inactive_pol to select output mode, duty polarity and inactive polarity.
4. Set PWM_PERIOD and PWM_DUTY register.
5. Set PWM_RPT.rpt_first_dimensional for reload operation (Optional).
6. Set PWM_CTRL.pwm_mode to 2'b01 to select continuous mode.
7. Set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b1 to enable the channel.
8. Set PWM_PERIOD and DUTY, then set PWM_ENABLE.pwm_ctrl_update_en to 1'b1 to update configuration (Optional).
9. If user want to disable PWM channel, set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b0.

31.6.4 PWM One-shot Mode Standard Usage Flow

1. Set PWM_ENABLE.pwm_en to 1'b0 to disable the PWM channel.
2. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel to configure the clock selection and division.
3. Set PWM_CTRL.output_mode/duty_pol/inactive_pol to select output mode, duty polarity and inactive polarity.
4. Set PWM_PERIOD and PWM_DUTY register.
5. Set PWM_RPT.rpt_first_dimensional for reload operation (Option).
6. Set PWM_RPT.rpt_second_dimensional.
7. Set PWM_CTRL.pwm_mode to 2'b00 to select one shot mode.
8. Set INT_EN.oneshot_end_int_en to 1'b1 to enable interrupt.
9. Set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b1 to enable the channel.
10. When an interrupt is asserted, refer to PWM_INTSTS register to know the raw interrupt. User should set 1'b1 to correspond bit of PWM_INTSTS to clear the interrupt. PWM_CTRL.pwm_en/pwm_clk_en is automatically cleared.

31.6.5 Multi-channel Synchronous Start Usage Flow

1. Set PWM_ENABLE.pwm_en of all synchronous channels to 1'b0 to disable the PWM channel.
2. Set PWM_CTRL.pwm_mode/output_mode/duty_pol/inactive_pol, PWM_PERIOD and PWM_DUTY register of all synchronous channels.
3. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel of channel 0 to configure the clock selection and division.
4. Set PWM_Enable.pwm_global_join_en of all synchronous channels to 1'b1.
5. Enable the INT_EN.oneshot_end_int_en of channel 0 to enable interrupt generation if the channel is desired to work in the one-shot mode.
6. Set PWM_ENABLE.pwm_clk_en of channel 0 to 1'b1 to enable clock.
7. Set PWM_GLOBAL_ARBITER.global_grant to 8'h01 to set channel 0 as main channel.
8. Set PWM_GLOBAL_CTRL.global_pwm_en to enable all synchronous channels.
9. Set PWM_PERIOD and DUTY to all synchronous channel, then set PWM_GLOBAL_CTRL.global_pwm_ctrl_update_en to 1'b1 to update configuration of all synchronous channels (Optional).
10. If user want to disable PWM channel, set PWM_GLOBAL_CTRL.global_pwm_en to 1'b0, then set PWM_CTRL.pwm_clk_en of channel 0 to 1'b0 to disable clock.

31.6.6 IR transmission Usage Flow

1. Set PWM_CTRL.pwm_en to 1'b0 to disable the PWM channel.
2. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel to configure the clock selection and

Rockchip Confidencial

division. The clock frequency should be 1 MHz after division.
3. Set PWM_CTRL.pwm_clk_en to 1'b1 to enable clock.
4. Set PWM_IR_TRANS_ARBITER.ir_trans_grant to 8'b01 to set channel 0 for transmission.
5. Set PWM_IR_TRANS_CTRL0.format/it_trans_mode/ir_trans_duty_pol/ ir_trans_length_within_one_frame/it_trans_inactive_pol
6. Set PWM_IR_TRANS_DATA_VALUE.ir_trans_out_value to the data which need to transmit.
7. Set the PWM_IR_TRANS_CTRL0.ir_trans_rpt if the channel is desired to work in the one-shot mode.
8. Set PWM_IR_TRANS_CTRL0.transout_en to 1'b1 to enable PWM IR transmission.
9. If user want to disable the output waveform, set PWM_IR_TRANS_CTRL0.transout_en to 1'b0, the channel will be disable at the end of one frame.

31.6.7 Clock Counter Usage Flow

1. Set PWM_COUNTER_ARBITER.counter_grant to 8'h01 to use channel 0.
2. Set PWM_COUNTER_CTRL.counter_clk_sel/counter_channel_sel to select clock.
3. Set PWM_COUNTER_CTRL.counter_en to 1'b1 to enable clock counter.
4. Refer to PWM_COUNTER_LOW/ PWM_COUNTER_HIGH to gets the counter value.
5. If user want to disable clock counter, set PWM_COUNTER_CTRL.counter_en to 1'b0, then set PWM_COUNTER_ARBITER.counter_grant to 8'h0.

31.6.8 Clock Frequency Meter Usage Flow

1. Set PWM_FREQ_ARBITER.freq_grant to 8'h01 to use channel 0.
2. Set PWM_FREQ_CTRL.freq_clk_sel/freq_channel_sel to select clock.
3. Set PWM_FREQ_CTRL.freq_timer_clk_sel to select timer clock.
4. Set PWM_FREQ_TIMER_VALUE.freq_timer_value to set timer.
5. Set PWM_INT_EN.freq_int_en to enable interrupt.
6. Set PWM_FREQ_CTRL.freq_en to 1'b1 to enable clock frequency meter.
7. When an interrupt is asserted, refer to PWM_INTSTS register to know the raw interrupt. Then refer PWM_FREQ_RESULT_VALUE.freq_result_value to get result. The frequency can be calculated as formula: frequency_timer* freq_result_value/ freq_timer_value. User should set 1'b1 to correspond bit of PWM_INTSTS to clear the interrupt.
8. If user want to disable clock frequency meter, set PWM_FREQ_ARBITER.freq_grant to 8'h0.

31.6.9 Biphasic Counter Usage Flow

1. Set PWM_BIPHASIC_COUNTER_CTRL0.biphasic_counter_clk_sel to select clock.
2. Set PWM_BIPHASIC_COUNTER_CTRL0.biphasic_counter_mode to select mode.
3. Set PWM_BIPHASIC_COUNTER_CTRL1.biphasic_counter_filter_number/ biphasic_counter_filter_enable to set the filter.
4. Set PWM_BIPHASIC_COUNTER_TIMER_VALUE. biphasic_counter_timer_value to set timer.
5. Set PWM_INT_EN.biphasic_couner_int_en to enable interrupt.
6. Set PWM_BIPHASIC_COUNTER_CTRL0.biphasic_counter_en to 1'b1 to enable biphasic counter.
7. When an interrupt is asserted, refer to PWM_INTSTS register to know the raw interrupt. Then refer PWM_BIPHASIC_COUNTER_RESULT_VALUE to get the result. User should set 1'b1 to correspond bit of PWM_INTSTS to clear the interrupt.

31.6.10 Generates Waveform Through Lookup Table Usage Flow

1. Set PWM_ENABLE.pwm_en to 1'b0 to disable the PWM channel.
2. Set PWM_CLK_CTRL.prescale/scale/clk_src_sel to configure the clock selection and division.
3. Set PWM_CTRL.output_mode/duty_pol/inactive_pol to select output mode, duty polarity and inactive polarity.
4. Set PWM_PERIOD register, the value should be 1~256.
5. Set PWM_WAVE_CTRL.wave_duty_en to 1'b1 to enable duty to reload through lookup table.
6. Set PWM_WAVE_CTRL.wave_update_mode to 1'b1.
7. Set PWM_WAVE_MAX.wave_duty_max.
8. Set PWM_WAVE_MIN.wave_duty_min.

Rockchip Confidential

9. Set the duty value in lookup table from offset address wave_duty_min to wave_duty_max. The base address of lookup table is PWM_WAVE_MEM.
10. Set PWM_RPT.rpt_first_dimensional for reloading interval.
11. Set PWM_CTRL.pwm_mode to 2'b01 to select continuous mode.
12. Set PWM_ENABLE.pwm_en/pwm_clk_en to 1'b1 to enable the channel.

Rockchip Confidencial

Chapter 32 Inter-Integrated Circuit (I2C)

32.1 Overview

The Inter-Integrated Circuit (I2C) is a two wired (SCL and SDA), bi-directional serial bus that provides an efficient and simple method of information exchange between devices. This I2C bus controller supports master mode acting as a bridge between AMBA protocol and generic I2C bus system.

I2C Controller supports the following features:

- Support 3 independent I2C: I2C0~2
- Item Compatible with I2C-bus
- AMBA APB slave interface
- Support master mode of I2C bus
- Software programmable clock frequency and transfer rate up to 400Kbit/sec
- Support 7 bits and 10 bits addressing modes
- Interrupt or polling driven multiple bytes data transfer
- Clock stretching and wait state generation
- Filter out glitch on SCL and SDA

32.2 Block Diagram

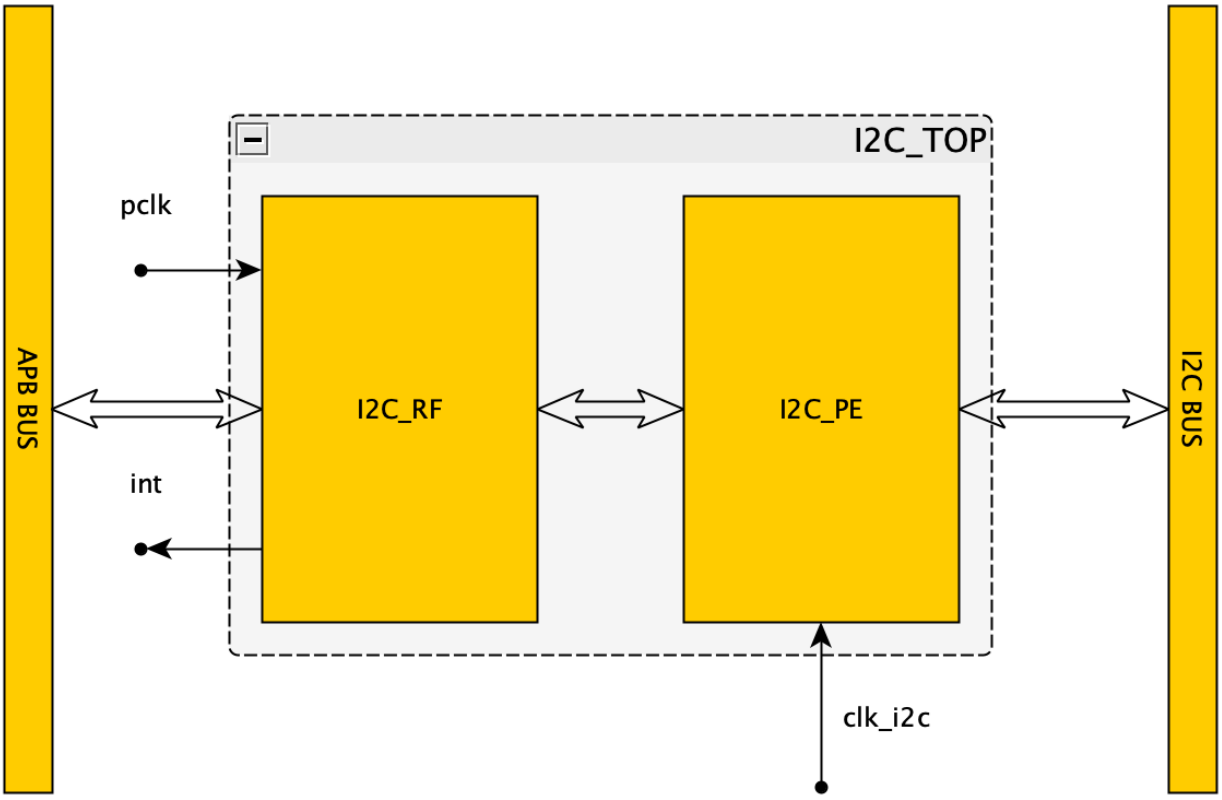

Fig.32-1 I2C Architecture

32.2.1 I2C_RF

I2C_RF module is used to control the I2C controller operation by the host with APB interface. It implements the register set and the interrupt functionality. The I2C_RF component operates synchronously with the APB clock.

32.2.2 I2C_PE

I2C_PE module implements the I2C master operation for transmit data to and receive data from other I2C devices. The I2C master controller operates synchronously with the clk_i2c.

32.2.3 I2C_TOP

I2C_TOP module is the top module of the I2C controller.

Confidential

32.3 Function Description

This chapter provides a description about the functions and behavior under various conditions.
The I2C controller supports only Master function. It supports the 7-bits/10-bits addressing mode and supports general call address. The maximum clock frequency and transfer rate can be up to 400Kbit/sec.
The operations of I2C controller is divided to 2 parts and described separately: initialization and master mode programming.

32.3.1 Initialization

The I2C controller is based on AMBA APB bus architecture and usually is part of a SOC. So before I2C operates, some system setting and configuration must be conformed, which includes:

- I2C interrupt connection type: CPU interrupt scheme should be considered. If the I2C interrupt is connected to extra Interrupt Controller module, we need decide the INTC vector.
- I2C Clock Rate: The I2C controller uses the APB clock to configure controller and uses clk_i2c as the working clock. The correct register setting is subject to the system requirement.

32.3.2 Master Mode Programming

- SCL Clock
  When the I2C controller is programmed in Master mode, the SCL frequency is determined by I2C_CLKDIV register. The SCL frequency is calculated by the following formula:
  SCL Divisor = 8*(CLKDIVL + 1 + CLKDIVH + 1); clk_i2c = 100MHz~200MHz.
  SCL = clk_i2c/ SCLK Divisor.

- Data Receiver Register Access
  When the I2C controller received MRXCNT bytes data, CPU can get the data through register RXDATA0 ~ RXDATA7. The controller can receive up to 32 bytes' data in one transaction.
  When MRXCNT register is written, the I2C controller will start to drive SCL to receive data.

- Transmit Transmitter Register
  Data to transmit are written to TXDATA0~7 by CPU. The controller can transmit up to 32 bytes' data in one transaction. The lower byte will be transmitted first.
  When MTXCNT register is written, the I2C controller will start to transmit data.

- Start Command
  Write 1 to I2C_CON[3], the controller will send I2C start command.

- Stop Command
  Write 1 to I2C_CON[4], the controller will send I2C stop command.

- I2C Operation mode
  There are four i2c operation modes.
  - When I2C_CON[2:1] is 2'b00, the controller will transmit all valid data in TXDATA0~TXDATA7 byte by byte. The controller will transmit lower byte first.
  - When I2C_CON[2:1] is 2'b01, the controller will transmit device address in MRXADDR first (Write/Read bit = 0) and then transmit device register address in MRXRADDR. After that, the controller will assert restart signal and resend MRXADDR (Write/Read bit = 1). At last, the controller enters receive mode.

Rockchip Confidential

- When I2C_CON[2:1] is 2'b10, the controller is in receive mode, it will trigger clock to read MRXCNT byte data.
- When I2C_CON[2:1] is 2'b11, the controller will transmit device address in MRXADDR first (Write/Read bit = 1) and then transmit device register address in MRXRADDR. After that, the controller will assert restart signal and resend MRXADDR (Write/Read bit = 1). At last, the controller enters receive mode.

- Read/Write Command
  - When I2C_OPMODE (I2C_CON[2:1]) is 2'b01 or 2'b11, the Read/Write command bit is decided by controller itself.
  - In RX only mode (I2C_CON[2:1] is 2'b10), the Read/Write command bit is decided by MRXADDR[0].
  - In TX only mode (I2C_CON[2:1] is 2'b00), the Read/Write command bit is decided by TXDATA[0].

- Master Interrupt Condition

  There are 7 interrupt bits in I2C_ISR register related to master mode.
  - Byte transmitted finish interrupt (Bit 0): The bit is asserted when Master completed transmitting a byte.
  - Byte received finish interrupt (Bit 1): The bit is asserted when Master completed receiving a byte.
  - MTXCNT bytes data transmitted finish interrupt (Bit 2): The bit is asserted when Master completed transmitting MTXCNT bytes.
  - MRXCNT bytes data received finish interrupt (Bit 3): The bit is asserted when Master completed receiving MRXCNT bytes.
  - Start interrupt (Bit 4): The bit is asserted when Master finished asserting start command to I2C bus.
  - Stop interrupt (Bit 5): The bit is asserted when Master finished asserting stop command to I2C bus.
  - NAK received interrupt (Bit 6): The bit is asserted when Master received a NAK handshake.

- Last byte acknowledge control
  - If I2C_CON[5] is 1, the I2C controller will transmit NAK handshake to slave when the last byte received in RX only mode.
  - If I2C_CON[5] is 0, the I2C controller will transmit ACK handshake to slave when the last byte received in RX only mode.

- How to handle NAK handshake received
  - If I2C_CON[6] is 1, the I2C controller will stop all transactions when NAK handshake received. And the software should take responsibility to handle the problem.
  - If I2C_CON[6] is 0, the I2C controller will ignore all NAK handshake received.

- I2C controller data transfer waveform
  - Bit transferring
    - Data Validity

      The SDA line must be stable during the high period of SCL, and the data on SDA line can only be changed when SCL is in low state.

Rockchip Confidencial

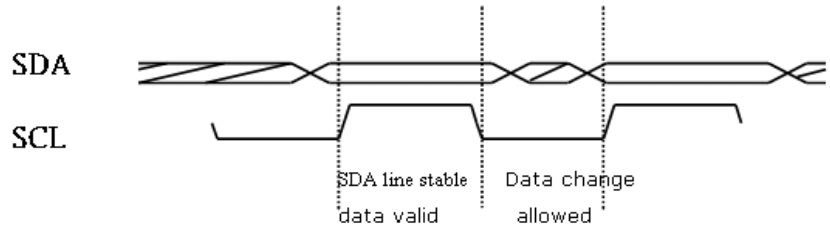

Fig.32-2 I2C DATA Validity

- START and STOP conditions
  START condition occurs when SDA goes low while SCL is in high period. STOP condition is generated when SDA line goes high while SCL is in high state.

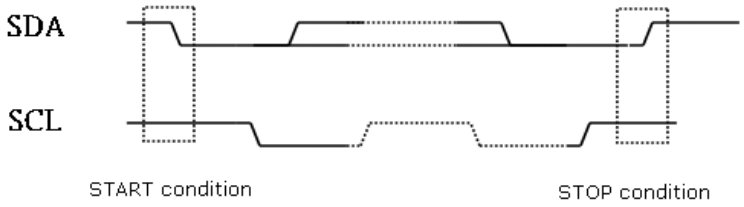

Fig.32-3 I2C Start and Stop Conditions

- Data transfer
  - Acknowledge
    After a byte of data transferring (clocks labeled as 1~8), in 9th clock the receiver must assert an ACK signal on SDA line, if the receiver pulls SDA line to low, it means "ACK", on the contrary, it's "NOT ACK".

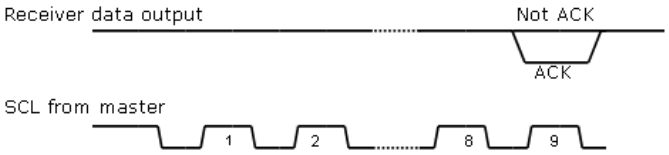

Fig.32-4 I2C Acknowledge

  - Byte transfer
    The master owns I2C bus might initiate multi byte to transfer to a slave. The transfer starts from a "START" command and ends in a "STOP" command. After every byte transfer, the receiver must reply an ACK to transmitter.

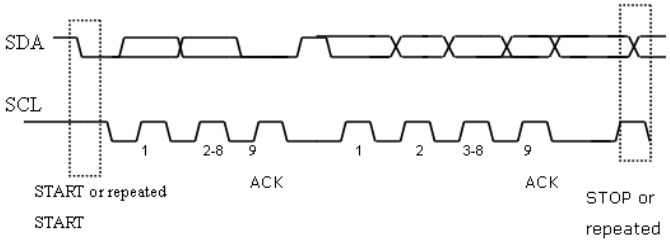

Fig.32-5 I2C Byte Transfer

32.4 Register Description

32.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Rockchip Confidential

Name	Base Address
I2C0	0xff040000
I2C1	0xff050000
I2C2	0xff060000

32.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
RKI2C_CON	0x0000	W	0x00060000	Control register
RKI2C_CLKDIV	0x0004	W	0x00000001	Clock divider register I2C CLK = PCLK / (16*CLKDIV)
RKI2C_MRXADDR	0x0008	W	0x00000000	The slave address accessed for master rx mode
RKI2C_MRXRADDR	0x000C	W	0x00000000	The slave register address accessed for master rx mode
RKI2C_MTXCNT	0x0010	W	0x00000000	Master transmit count, specify the total bytes to be transmit (0~32)
RKI2C_MRXCNT	0x0014	W	0x00000000	Master rx count, specify the total bytes to be received(0~32)
RKI2C_IEN	0x0018	W	0x00000000	Interrupt enable register
RKI2C_IPD	0x001C	W	0x00000000	Interrupt pending register
RKI2C_FCNT	0x0020	W	0x00000000	Finished count: the count of data which has been transmitted or received for debug purpose
RKI2C_SCL_OE_DB	0x0024	W	0x00000020	Slave hold debounce configure register
RKI2C_TXDATA0	0x0100	W	0x00000000	I2C tx data register 0
RKI2C_TXDATA1	0x0104	W	0x00000000	I2C tx data register 1

32.4.3 Detail Registers Description

RKI2C_CON

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:16	RO	0x0006	version Rki2c version information.
15:14	RW	0x0	stop_setup Stop setup configuration. TSU;sto = (stop_setup + 1) * T(SCL_HIGH) + Tclk_i2c.

Rockchip Confidential

Bit	Attr	Reset Value	Description
13:12	RW	0x0	start_setup Start setup config. TSU;sta = (start_setup + 1) * T(SCL_HIGH) + Tclk_i2c. THD;sta = (start_setup + 2) * T(SCL_HIGH) - Tclk_i2c.
11:8	RW	0x0	data_upd_st SDA update point config. Used to config sda change state when scl is low, used to adjust setup/hold time. 4'bn: Thold = (n + 1) * Tclk_i2c. Note: 0 <= n <= 5
7	RO	0x0	reserved
6	RW	0x0	act2nak Operation when NAK handshake is received. 1'b0: Ignored. 1'b1: Stop transaction.
5	RW	0x0	ack Last byte acknowledge control in master receive mode. 1'b0: ACK 1'b1: NAK
4	RW	0x0	stop Stop enable, when this bit is written to 1, I2C will generate stop signal.
3	RW	0x0	start Start enable, when this bit is written to 1, I2C will generate start signal.
2:1	RW	0x0	i2c_mode I2c mode select. 2'b00: Transmit only. 2'b01: Transmit address (device + register address) --> Restart --> Transmit address -> Receive only. 2'b10: Receive only. 2'b11: Transmit address (device + register address, write/read bit is 1) --> Restart --> Transmit address (device address) --> Receive data.
0	RW	0x0	i2c_en I2c module enable. 1'b0: Disable 1'b1: Enable

RKI2C_CLKDIV

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	CLKDIVH SCL high level clock count. T(SCL_HIGH) = Tclk_i2c * (CLKDIVH + 1) * 8.
15:0	RW	0x0001	CLKDIVL SCL low level clock count. T(SCL_LOW) = Tclk_i2c * (CLKDIVL + 1) * 8.

RKI2C_MRXADDR

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:27	RO	0x00	reserved

Rockchip Confidencial

Bit	Attr	Reset Value	Description
26	RW	0x0	addhvld Address high byte valid. 1'b0: Invalid 1'b1: Valid
25	RW	0x0	addmvld Address middle byte valid. 1'b0: Invalid 1'b1: Valid
24	RW	0x0	addlvld Address low byte valid. 1'b0: Invalid 1'b1: Valid
23:0	RW	0x000000	saddr Master address register. The lowest bit indicate write or read. 24 bits address register.

RKI2C_MRXRADDR

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:27	RO	0x00	reserved
26	RW	0x0	sraddhvld Address high byte valid. 1'b0: Invalid 1'b1: Valid
25	RW	0x0	sraddmvld Address middle byte valid. 1'b0: Invalid 1'b1: Valid
24	RW	0x0	sraddlvld Address low byte valid. 1'b0: Invalid 1'b1: Valid
23:0	RW	0x000000	sraddr Slave register address accessed. 24 bits register address

RKI2C_MTXCNT

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RW	0x00	mtxcnt Master transmit count. 6 bits counter

RKI2C_MRXCNT

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RW	0x00	mrxcnt Master rx count. 6 bits counter

RKI2C_IEN

Address: **Operational Base** + offset (0x0018)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:9	RO	0x000000	reserved
8	RW	0x0	slavehdsdaen Slave hold sda interrupt enable. 1'b0: Disable 1'b1: Enable
7	RW	0x0	slavehdsclen Slave hold scl interrupt enable. 1'b0: Disable 1'b1: Enable
6	RW	0x0	nakrcvien NAK handshake received interrupt enable. 1'b0: Disable 1'b1: Enable
5	RW	0x0	stopien Stop operation finished interrupt enable. 1'b0: Disable 1'b1: Enable
4	RW	0x0	startien Start operation finished interrupt enable. 1'b0: Disable 1'b1: Enable
3	RW	0x0	mbrfien MRXCNT data received finished interrupt enable. 1'b0: Disable 1'b1: Enable
2	RW	0x0	mbtfien MTXCNT data transfer finished interrupt enable. 1'b0: Disable 1'b1: Enable
1	RW	0x0	brfien Byte rx finished interrupt enable. 1'b0: Disable 1'b1: Enable
0	RW	0x0	btfien Byte tx finished interrupt enable. 1'b0: Disable 1'b1: Enable

RKI2C_IPD

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:9	RO	0x000000	reserved
8	RW	0x0	slavehdsdaipd Slave hold sda interrupt pending bit. 1'b0: No interrupt available. 1'b1: Slave hold sda interrupt appear, write 1 to clear.
7	RW	0x0	slavehdsclipd Slave hold scl interrupt pending bit. 1'b0: No interrupt available. 1'b1: Slave hold scl interrupt appear, write 1 to clear.
6	W1C	0x0	nakrcvipd NAK handshake received interrupt pending bit. 1'b0: No interrupt available. 1'b1: NAK handshake received interrupt appear, write 1 to clear.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
5	W1C	0x0	stopipd Stop operation finished interrupt pending bit. 1'b0: No interrupt available. 1'b1: Stop operation finished interrupt appear, write 1 to clear.
4	W1C	0x0	startipd Start operation finished interrupt pending bit. 1'b0: No interrupt available. 1'b1: Start operation finished interrupt appear, write 1 to clear.
3	W1C	0x0	mbrfipd MRXCNT data received finished interrupt pending bit. 1'b0: No interrupt available. 1'b1: MRXCNT data received finished interrupt appear, write 1 to clear.
2	W1C	0x0	mbtfipd MTXCNT data transfer finished interrupt pending bit. 1'b0: No interrupt available. 1'b1: MTXCNT data transfer finished interrupt appear, write 1 to clear.
1	W1C	0x0	brfipd Byte rx finished interrupt pending bit. 1'b0: No interrupt available. 1'b1: Byte rx finished interrupt appear, write 1 to clear.
0	W1C	0x0	btfipd Byte tx finished interrupt pending bit. 1'b0: No interrupt available. 1'b1: Byte tx finished interrupt appear, write 1 to clear.

RKI2C_FCNT

Address: **Operational Base** + offset (0x0020)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RO	0x00	fcnt The count of data which has been transmitted or received for debug purpose.

RKI2C_SCL_OE_DB

Address: **Operational Base** + offset (0x0024)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x20	scl_oe_db Slave hold scl debounce. Cycles for debounce (unit: Tclk_i2c).

RKI2C_TXDATA0

Address: **Operational Base** + offset (0x0100)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata0 Data0 to be transmitted. 32 bits data

RKI2C_TXDATA1

Address: **Operational Base** + offset (0x0104)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata1 Data1 to be transmitted. 32 bits data

RKI2C_TXDATA2

Address: **Operational Base** + offset (0x0108)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata2 Data2 to be transmitted. 32 bits data

RKI2C_TXDATA3

Address: **Operational Base** + offset (0x010C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata3 Data3 to be transmitted. 32 bits data

RKI2C_TXDATA4

Address: **Operational Base** + offset (0x0110)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata4 Data4 to be transmitted. 32 bits data

RKI2C_TXDATA5

Address: **Operational Base** + offset (0x0114)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata5 Data5 to be transmitted. 32 bits data

RKI2C_TXDATA6

Address: **Operational Base** + offset (0x0118)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata6 Data6 to be transmitted. 32 bits data

RKI2C_TXDATA7

Address: **Operational Base** + offset (0x011C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	txdata7 Data7 to be transmitted. 32 bits data

RKI2C_RXDATA0

Address: **Operational Base** + offset (0x0200)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata0 Data0 received. 32 bits data

RKI2C_RXDATA1

Address: **Operational Base** + offset (0x0204)

Rockchip Confidencial

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata1 Data1 received. 32 bits data

RKI2C_RXDATA2

Address: **Operational Base** + offset (0x0208)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata2 Data2 received. 32 bits data

RKI2C_RXDATA3

Address: **Operational Base** + offset (0x020C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata3 Data3 received. 32 bits data

RKI2C_RXDATA4

Address: **Operational Base** + offset (0x0210)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata4 Data4 received. 32 bits data

RKI2C_RXDATA5

Address: **Operational Base** + offset (0x0214)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata5 Data5 received. 32 bits data

RKI2C_RXDATA6

Address: **Operational Base** + offset (0x0218)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata6 Data6 received. 32 bits data

RKI2C_RXDATA7

Address: **Operational Base** + offset (0x021C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	rxdata7 Data7 received. 32 bits data

RKI2C_ST

Address: **Operational Base** + offset (0x0220)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	RO	0x0	scl_st SCL status. 1'b0: SCL status low. 1'b0: SCL status high.

Rockchip Confidencial

Bit	Attr	Reset Value	Description
0	RO	0x0	sda_st SDA status. 1'b0: SDA status low. 1'b0: SDA status high.

RKI2C_DBGCTRL

Address: **Operational Base** + offset (0x0224)

Bit	Attr	Reset Value	Description
31:15	RO	0x00000	reserved
14	RW	0x0	h0_check_scl 1'b0: Check if scl been pull down by slave at the whole SCL_HIGH. 1'b1: Check if scl been pull down by slave only at the h0 of SCL_HIGH(SCL_HIGH including h0~h7).
13	RW	0x0	nak_release_scl 1'b0: Hold scl as low when received nack. 1'b1: Release scl as high when received nack.
12	RW	0x0	flt_en SCL edge glitch filter enable. 1'b0: Disable 1'b1: Enable
11:8	RW	0x0	slv_hold_scl_th Slave hold scl threshold = slv_hold_scl_db * Tclk_i2c.
7:4	RW	0x0	flt_r Filter scl rising edge glitches of width less than flt_r * Tclk_i2c.
3:0	RW	0x0	flt_f Filter scl falling edge glitches of width less than flt_f * Tclk_i2c.

RKI2C_CON1

Address: **Operational Base** + offset (0x0228)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved
2	RW	0x0	auto_stop_nak Auto stop when i2c master received nak from slave. Work when CON1[0]=1'b1. 1'b0: Do not auto stop when received nak. 1'b1: Auto stop when received nak.
1	RW	0x0	auto_stop_tx_end Auto stop when i2c master tx end. Work when CON1[0]=1'b1. 1'b0: Do not auto stop when tx end. 1'b1: Auto stop when tx end.
0	RW	0x0	auto_stop Auto stop when i2c master received nak from slave or tx end. 1'b0: Do not auto stop when received nak or tx end. 1'b1: Auto stop when received nak or tx end.

32.6 Application Notes

The I2C controller core operation flow chart below is to describe how the software configures and performs an I2C transaction through this I2C controller core. Descriptions are divided into 3 sections, transmit only mode, receive only mode, and mix mode. Users are strongly advised to follow:

- Transmit only mode (I2C_CON[1:0]=2'b00)

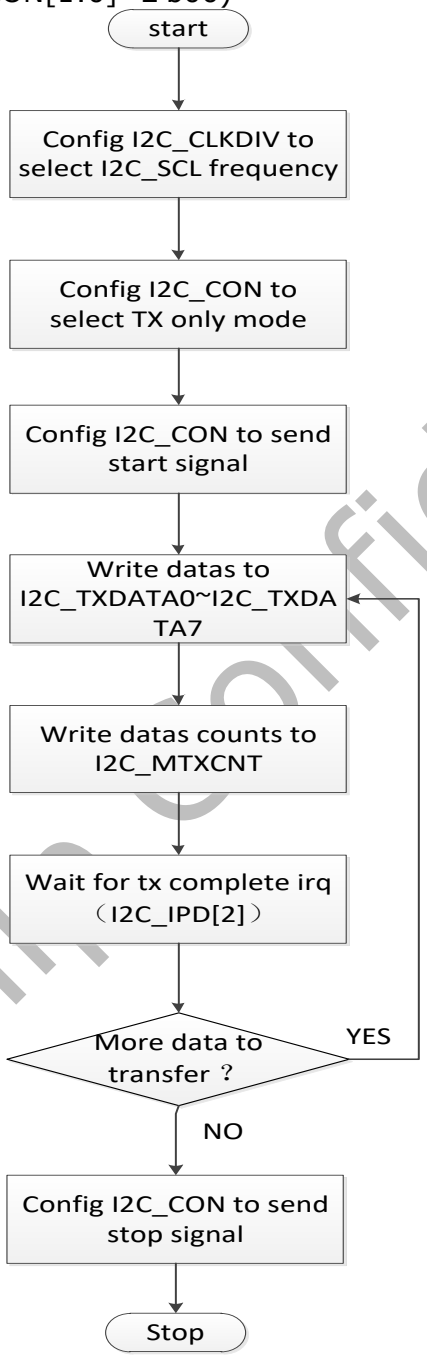

Fig.32-6 I2C Flow Chat for Transmit Only Mode

Rockchip Confidential

- Receive only mode (I2C_CON[1:0]=2'b10)

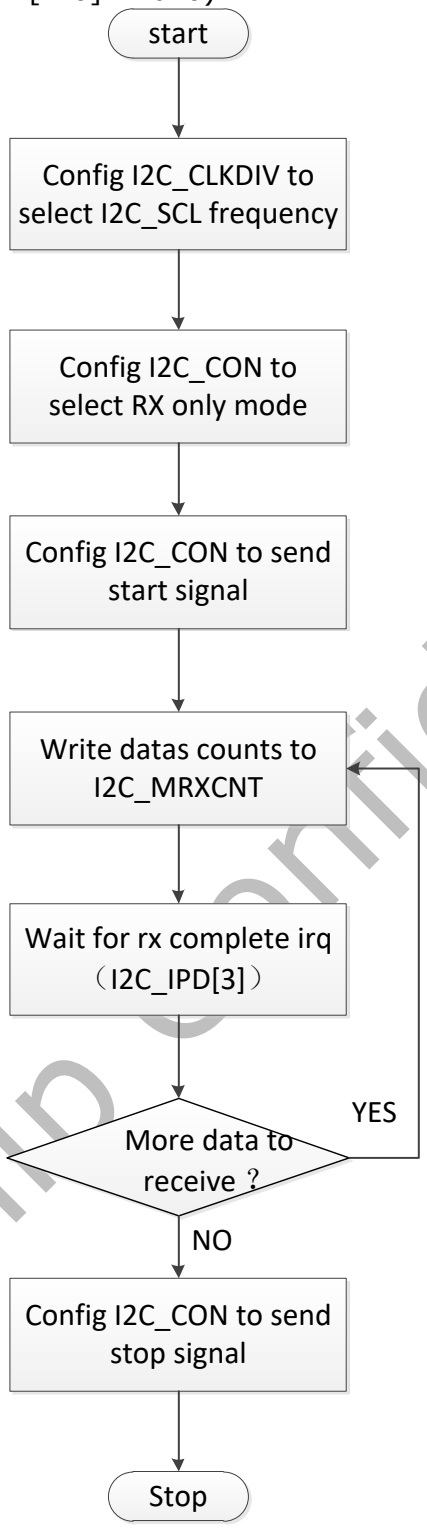

Fig.32-7 I2C Flow Chat for Receive Only Mode

Rockchip Confidential

- Mix mode (I2C_CON[1:0]=2'b01 or I2C_CON[1:0]=2'b11)

Chapter 33 Universal Asynchronous Receiver/Transmitter

33.1 Overview

The Universal Asynchronous Receiver/Transmitter (UART) is used for serial communication with a peripheral, modem (data carrier equipment, DCE) or data set. Data is written from a master (CPU) over the APB bus to the UART and it is converted to serial form and transmitted to the destination device. Serial data is also received by the UART and stored for the master (CPU) to read back.

UART Controller supports the following features:

- Support 6 independent UART controllers: UART0-UART5
- Support APB Slave configuration interface of 8, 16, 32bits
- All contain two 64 Bytes FIFOs for data receive and transmit
- UART3-UART5 support auto flow-control
- UART3-UART5 support RS485 function
- Support bit rates 115.2Kbps, 460.8Kbps, 921.6Kbps, 1.5Mbps, 3Mbps, 4Mbps, 8Mbps
- Support programmable baud rates, even with non-integer clock divider
- Standard asynchronous communication bits (start, stop and parity)
- Support interrupt-based or DMA-based mode
- Support 5-8 bits width transfer

33.2 Block Diagram

This section provides a description about the functions and behavior under various conditions. The UART Controller comprises with:

- AMBA APB interface
- FIFO controllers
- Register block
- Modem synchronization block and baud clock generation block
- Serial receiver and serial transmitter

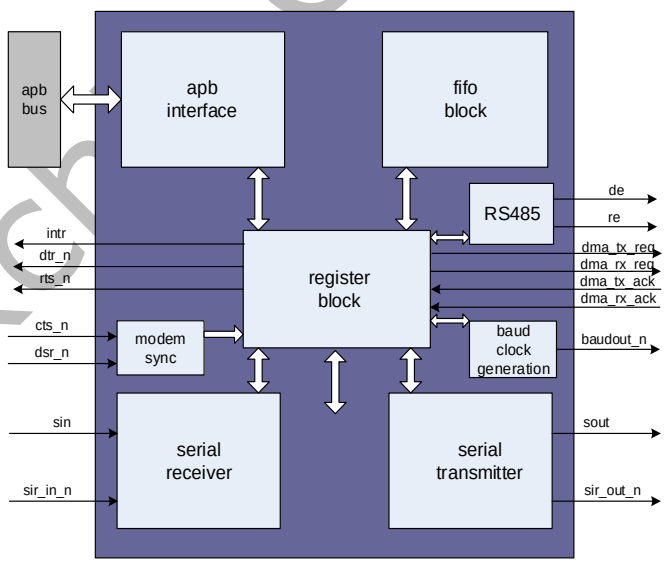

Fig. 33-1 UART Architecture

APB INTERFACE

The host processor accesses data, control, and status information on the UART through the APB interface. The UART supports APB data bus widths of 8, 16, and 32 bits.

Register block

Be responsible for the main UART functionality including control, status and interrupt generation.

Rockchip Confidential

Modem Synchronization block
Synchronizes the modem input signal.

FIFO block
Be responsible for FIFO control and storage (when using internal RAM) or signaling to control external RAM (when used).

Baud Clock Generator
Generates the transmitter and receiver baud clock along with the output reference clock signal (baudout_n).

Serial Transmitter
Converts the parallel data, written to the UART, into serial form and adds all additional bits, as specified by the control register, for transmission.

Serial Receiver
Converts the serial data character (as specified by the control register) received to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block.

33.3 Function Description

UART Serial Protocol
Because the serial communication is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to perform simple error checking on the received data, as shown in Figure.

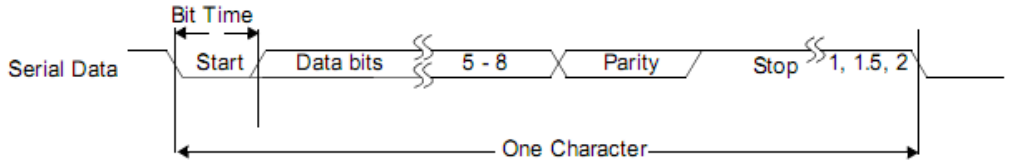

Fig. 33-2 UART Serial protocol

Baud Clock
The baud rate is controlled by the serial clock (sclk or pclk in a single clock implementation) and the Divisor Latch Register (DLH and DLL). As the exact number of baud clocks that each bit was transmitted for is known, calculating the mid-point for sampling is not difficult, that is every 16 baud clocks after the mid-point sample of the start bit.

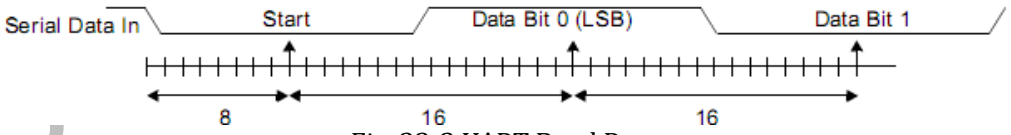

Fig. 33-3 UART Baud Rate

FIFO Support
1. NONE FIFO MODE
If FIFO support is not selected, then no FIFOs are implemented and only a single receive data byte and transmit data byte can be stored at a time in the RBR and THR.

2. FIFO MODE
The FIFO depth of is 64bytes. The FIFO mode of all the UART is enabled by register FCR[0].

Interrupts
The following interrupt types can be enabled with the IER register.
- Receiver Error
- Receiver Data Available
- Character Timeout (in FIFO mode only)

Rockchip Confidential

- Transmitter Holding Register Empty at/below threshold (in Programmable THRE Interrupt mode)
- Modem Status

DMA Support

The UART supports DMA signaling with the use of two output signals (dma_tx_req_n and dma_rx_req_n) to indicate when data is ready to be read or when the transmit FIFO is empty.

The dma_tx_req_n signal is asserted under the following conditions:

- When the Transmitter Holding Register is empty in non-FIFO mode.
- When the transmitter FIFO is empty in FIFO mode with Programmable THRE interrupt mode disabled.
- When the transmitter FIFO is at, or below the programmed threshold with Programmable THRE interrupt mode enabled.

The dma_rx_req_n signal is asserted under the following conditions:

- When there is a single character available in the Receive Buffer Register in non-FIFO mode.
- When the Receiver FIFO is at or above the programmed trigger level in FIFO mode.

Auto Flow Control

The UART can be configured to have a 16750-compatible Auto RTS and Auto CTS serial data flow control mode available. If FIFOs are not implemented, then this mode cannot be selected. When Auto Flow Control mode has been selected, it can be enabled with the Modem Control Register (MCR[5]). Following figure shows a block diagram of the Auto Flow Control functionality.

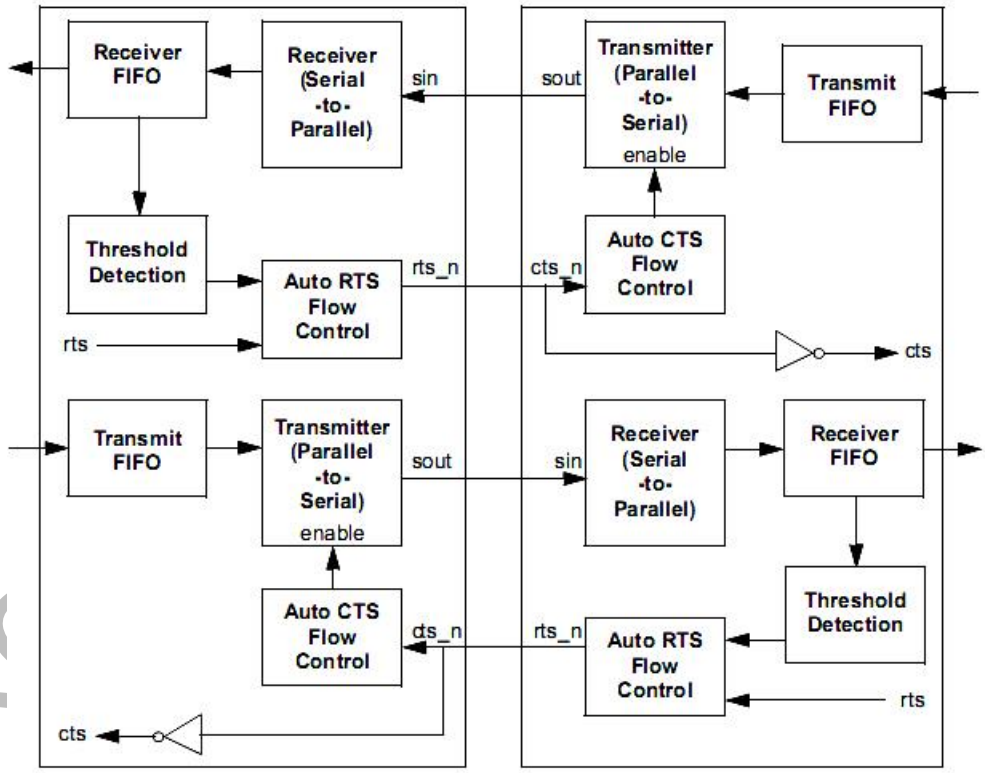

Fig. 33-4 UART Auto Flow Control Block Diagram

Auto RTS – Becomes active when the following occurs:

- Auto Flow Control is selected during configuration
- FIFOs are implemented
- RTS (MCR[1] bit and MCR[5]bit are both set)
- FIFOs are enabled (FCR[0]) bit is set)
- SIR mode is disabled (MCR[6] bit is not set)

Rockchip Confidential

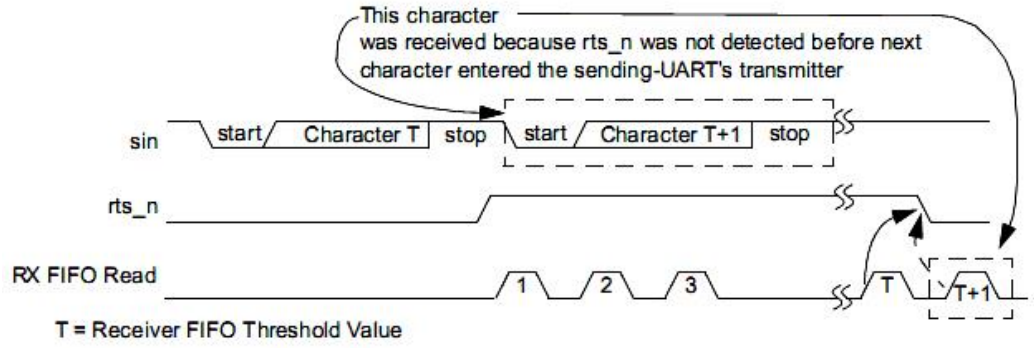

Fig. 33-5 UART AUTO RTS TIMING

Auto CTS – becomes active when the following occurs:

- Auto Flow Control is selected during configuration
- FIFOs are implemented
- AFCE (MCR[5] bit is set)
- FIFOs are enabled through FIFO Control Register FCR[0] bit
- SIR mode is disabled (MCR[6] bit is not set)

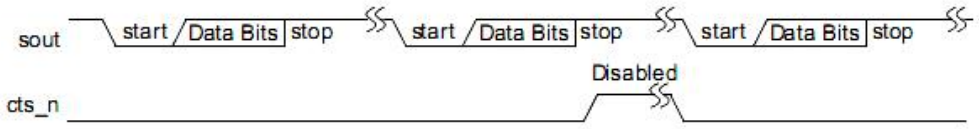

Fig. 33-6 UART AUTO CTS TIMING

RS485 Mode

The RS485 standard supports serial communication over a twisted pair configuration. The difference between the RS232 and RS485 standards is its use of a balanced line for transmission. This usage is also known as the differential format that sends the same signal on two separate lines with phase delay and then compares the signals at the end, subtracts any noise, and adds them to regain signal strength. This process allows the RS485 standard to be viable over significantly longer distances than its short range RS232 counterpart.

UART supports hardware mode and software mode.

- Hardware mode, DE and RE are mutually exclusive. By default 'de' and 're' will be disabled. When at user mode, user should programs the DE to active the 'de', while at auto mode, DE will assert when transfer starts. Once the TX FIFO becomes empty and the stop bit be sampled, 're' signal gets enabled and 'de' signal will be disabled, automatically. In this mode, hardware will consider the de-inactive timing and turn around timing, which are programmed in the DET and TAT register, respectively. When 'de' is valid, it is useless to configure RE, and vice versa.
- Software mode, transmit and receive can happen simultaneously. The user can enable DE, RE at any point of time. Turn around timing as programmed in the TAT register and de-inactive timing as programmed in the DET are not applicable in this mode.

33.4 Register Description

33.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
UART0	0xff0a0000
UART1	0xff0b0000
UART2	0xff0c0000
UART3	0xff0d0000
UART4	0xff0e0000

Rockchip Confidential

Name	Base Address
UART5	0xff4e0000

33.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
UART_RBR	0x0000	W	0x00000000	Receive Buffer Register
UART_DLL	0x0000	W	0x00000000	Divisor Latch Low

33.4.3 Detail Registers Description

UART_RBR

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
7:0	RO	0x00	data_input Data byte received on the serial input port (sin) in UART mode, or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line Status Register (LCR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an over-run error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO is preserved, but any incoming data are lost and an over-run error occurs.

UART_DLL

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x00	baud_rate_divisor_l Lower 8 bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit (LCR[7]) is set and the UART is not busy (USR[0] is zero). The output baud rate is equal to the serial clock (pclk if one clock design, sclk if two clock design (CLOCK_MODE == Enabled)) frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor). Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLL is set, at least 8 clock cycles of the slowest UART clock should be allowed to pass before transmitting or receiving data.

UART_THR

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	WO	0x00	data_output Data to be transmitted on the serial output port (sout) in UART mode or the serial infrared output (sir_out_n) in infrared mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] = 0) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] = 1) and THRE is set, 64 characters of data may be written to the THR before the FIFO is full.. Any attempt to write data when the FIFO is full results in the write data being lost.

UART_DLH

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
7:0	RW	0x00	baud_rate_divisor_h Upper 8-bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit (LCR[7]) is set and the UART is not busy (USR[0] is zero). The output baud rate is equal to the serial clock (pclk if one clock design, sclk if two clock design CLOCK_MODE == Enabled)) frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor). Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLH is set, at least 8 clock cycles of the slowest UART clock should be allowed to pass before transmitting or receiving data.

UART_IER

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7	RW	0x0	prog_thre_int_en Programmable THRE Interrupt Mode Enable that can be written to only when THRE_MODE_USER == Enabled, always readable. This is used to enable/disable the generation of THRE Interrupt. 1'b0: Disabled 1'b1: Enabled
6:4	RO	0x0	reserved
3	RW	0x0	modem_status_int_en Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt. 1'b0: Disabled 1'b1: Enabled
2	RW	0x0	receive_line_status_int_en Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt. 1'b0: Disabled 1'b1: Enabled
1	RW	0x0	trans_hold_empty_int_en Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt. 1'b0: Disabled 1'b1: Enabled
0	RW	0x0	receive_data_available_int_en Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFOs enabled). These are the second highest priority interrupts. 1'b0: Disabled 1'b1: Enabled

UART_FCR

Rockchip Confidential

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:6	WO	0x0	rcvr_trigger At which the Received Data Available Interrupt is generated. In auto flow control mode it is used to determine when the rts_n signal is de-asserted. It also determines when the dma_rx_req_n signal is asserted in certain modes of operation. For details on DMA support, refer to "DMA Support". The following trigger levels are supported: 2'b00: 1 character in the FIFO 2'b01: FIFO 1/4 full 2'b10: FIFO 1/2 full 2'b11: FIFO 2 less than full
5:4	WO	0x0	tx_empty_trigger TX Empty Trigger. Writes have no effect when THRE_MODE_USER == Disabled. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. It also determines when the dma_tx_req_n signal is asserted when in certain modes of operation. For details on DMA support, refer to "DMA Support". The following trigger levels are supported: 2'b00: FIFO empty 2'b01: 2 characters in the FIFO 2'b10: FIFO 1/4 full 2'b11: FIFO 1/2 full
3	WO	0x0	dma_mode DMA Mode. This determines the DMA signaling mode used for the dma_tx_req_n and dma_rx_req_n output signals when additional DMA handshaking signals are not selected (DMA_EXTRA == No). For details on DMA support, refer to DMA Support. 1'b0: Mode 0 1'b1: Mode 1
2	WO	0x0	xmit_fifo_reset XMIT FIFO Reset. This resets the control portion of the transmit FIFO and treats the FIFO as empty. This also de-asserts the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit.
1	WO	0x0	rcvr_fifo_reset RCVR FIFO Reset. This resets the control portion of the receive FIFO and treats the FIFO as empty. This also de-asserts the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit.
0	WO	0x0	fifo_en FIFO Enable. This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFOs is reset.

UART_IIR

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
7:6	RO	0x0	fifos_en FIFOs Enabled. This is used to indicate whether the FIFOs are enabled or disabled. 2'b00: Disabled 2'b11: Enabled
5:4	RO	0x0	reserved
3:0	RO	0x1	int_id Interrupt ID. This indicates the highest priority pending interrupt which can be one of the following types: 4'b0000: Modem status 4'b0001: No interrupt pending 4'b0010: THR empty 4'b0100: Received data available 4'b0110: Receiver line status 4'b0111: Busy detect 4'b1100: Character timeout The interrupt priorities are split into four levels that are detailed in Table X. Bit 3 indicates an interrupt can only occur when the FIFOs are enabled and used to distinguish a Character Timeout condition interrupt.

UART_LCR

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7	RW	0x0	div_lat_access Divisor Latch Access Bit. Writeable only when UART is not busy (USR[0] is zero), always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.
6	RW	0x0	break_ctrl Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	RW	0x0	stick_parity If UART_16550_COMPATIBLE = NO, then writeable only when UART is not busy (USR[0] is 0); otherwise always writable and always readable. This bit is used to force parity value. When PEN, EPS and Stick Parity are set to 1, the parity bit is transmitted and checked as logic 0. If PEN and Stick Parity are set to 1 and EPS is a logic 0, then parity bit is transmitted and checked as a logic 1. If this bit is set to 0, Stick Parity is disabled.
4	RW	0x0	even_parity_sel Even Parity Select. Writeable only when UART is not busy (USR[0] is zero), always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked.

Rockchip Confidential

Bit	Attr	Reset Value	Description
3	RW	0x0	parity_en Parity Enable. Writeable only when UART is not busy (USR[0] is zero), always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively. 1'b0: Parity disabled 1'b1: Parity enabled
2	RW	0x0	stop_bits_num Number of stop bits. Writeable only when UART is not busy (USR[0] is zero), always readable. This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit. 1'b0: 1 stop bit. 1'b1: 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit.
1:0	RW	0x0	data_length_sel Data Length Select. Writeable only when UART is not busy (USR[0] is zero), always readable. This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected areas follows: 2'b00: 5 bits 2'b01: 6 bits 2'b10: 7 bits 2'b11: 8 bits

UART_MCR

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:7	RO	0x0000000	reserved
6	RW	0x0	sir_mode_en SIR Mode Enable. Writeable only when SIR_MODE == Enabled, always readable. This is used to enable/disable the IrDA SIR Mode features as described in "IrDA 1.0 SIR Protocol". 1'b0: IrDA SIR Mode disabled 1'b1: IrDA SIR Mode enabled
5	RW	0x0	auto_flow_ctrl_en Auto Flow Control Enable. Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in "Auto Flow Control". 1'b0: Auto Flow Control Mode disabled 1'b1: Auto Flow Control Mode enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
4	RW	0x0	loopback LoopBack Bit. This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	RW	0x0	out2 OUT2. This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is: 1'b0: Out2_n de-asserted (logic 1) 1'b1: Out2_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	RW	0x0	out1 OUT1. This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is: 1'b0: Out1_n de-asserted (logic 1) 1'b1: Out1_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.
1	RW	0x0	req_to_send Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high.In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input.
0	RW	0x0	data_terminal_ready Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is: 1'b0: dtr_n de-asserted (logic 1) 1'b1: dtr_n asserted (logic 0) The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive

Rockchip Confidential

UART_LSR

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7	RO	0x0	receiver_fifo_error Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. 1'b0: No error in RX FIFO 1'b1: Error in RX FIFO This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.
6	RO	0x1	trans_empty Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	RO	0x1	trans_hold_reg_empty Transmit Holding Register Empty bit. If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	RO	0x0	break_int Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read.

Rockchip Confidential

Bit	Attr	Reset Value	Description
3	RO	0x0	framing_error Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 1'b0: No framing error 1'b1: Framing error Reading the LSR clears the FE bit.
2	RO	0x0	parity_error Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 1'b0: No parity error 1'b1: Parity error Reading the LSR clears the PE bit.
1	RO	0x0	overrun_error Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. 1'b0: No overrun error 1'b1: Overrun error Reading the LSR clears the OE bit.
0	RO	0x0	data_ready Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. 1'b0: No data ready 1'b1: Data ready This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode.

UART_MSR

Address: **Operational Base** + offset (0x0018)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
7	RO	0x0	data_carrior_detect Data Carrier Detect. This is used to indicate the current state of the modem control line dcd_n. This bit is the complement of dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. 1'b0: dcd_n input is de-asserted (logic 1) 1'b1: dcd_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2).
6	RO	0x0	ring_indicator Ring Indicator. This is used to indicate the current state of the modem control line ri_n. This bit is the complement of ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. 1'b0: ri_n input is de-asserted (logic 1) 1'b1: ri_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1).
5	RO	0x0	data_set_ready Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. This bit is the complement of dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the UART. 1'b0: dsr_n input is de-asserted (logic 1) 1'b1: dsr_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR).
4	RO	0x0	clear_to_send Clear to Send. This is used to indicate the current state of the modem control line cts_n. This bit is the complement of cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the UART. 1'b0: cts_n input is de-asserted (logic 1) 1'b1: cts_n input is asserted (logic 0) In Loopback Mode (MCR[4] = 1), CTS is the same as MCR[1] (RTS).
3	RO	0x0	delta_data_carrier_detect Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. 1'b0: No change on dcd_n since last read of MSR 1'b1: Change on dcd_n since last read of MSR Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] = 1), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit is set when the reset is removed if the dcd_n signal remains asserted.

Rockchip Confidential

Bit	Attr	Reset Value	Description
2	RO	0x0	trailing_edge_ring_indicator Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active-low to an inactive-high state) has occurred since the last time the MSR was read. 1'b0: No change on ri_n since last read of MSR 1'b1: Change on ri_n since last read of MSR Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] = 1), TERI reflects when MCR[2] (Out1) has changed state from a high to a low.
1	RO	0x0	delta_data_set_ready Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. 1'b0: No change on dsr_n since last read of MSR 1'b1: Change on dsr_n since last read of MSR Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] = 1), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit is set when the reset is removed if the dsr_n signal remains asserted.
0	RO	0x0	delta_clear_to_send Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. 1'b0: No change on ctsdsr_n since last read of MSR 1'b1: Change on ctsdsr_n since last read of MSR Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] = 1), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit is set when the reset is removed if the cts_n signal remains asserted.

UART_SCR

Address: **Operational Base** + offset (0x001C)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x00	temp_store_space Scratchpad register. This register is for programmers to use as a temporary storage space. It has no defined purpose in the UART.

UART_SRBR

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RO	0x00	shadow_rbr This is a shadow register for the RBR and has been allocated sixteen 32-bit locations (0x30-0x6c) so as to accommodate burst accesses from the master. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If in FIFO mode (FIFO_MODE !=

Rockchip Confidential

Bit	Attr	Reset Value	Description
			NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO are preserved, but any incoming data is lost. An overrun error also occurs.

UART_STHR

Address: **Operational Base** + offset (0x0030)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	WO	0x00	shadow_thr This is a shadow register for the THR and has been allocated sixteen 32-bit locations(0x30-0x6c) so as to accommodate burst accesses from the master. This register contains data to be transmitted on the serial output port (sout) in UART mode or the serial infrared output (sir_out_n) in infrared mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] set to zero) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] set to one) and THRE is set, x number of characters of data may be written to the THR before the FIFO is full. The number x (default=16) is determined by the value of FIFO Depth that you set during configuration. Any attempt to write data when the FIFO is full results in the write data being lost.

UART_FAR

Address: **Operational Base** + offset (0x0070)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	fifo_access_test_en Writes have no effect when FIFO_ACCESS == No, always readable. This register is use to enable a FIFO access mode for testing, so that the receive FIFO can be written by the master and the transmit FIFO can be read by the master when FIFOs are implemented and enabled. When FIFOs are not implemented or not enabled it allows the RBR to be written by the master and the THR to be read by the master. 1'b0: FIFO access mode disabled 1'b1: FIFO access mode enabled Note, that when the FIFO access mode is enabled/disabled, the control portion of the receive FIFO and transmit FIFO is reset and the FIFOs are treated as empty.

UART_TFR

Address: **Operational Base** + offset (0x0074)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
7:0	RO	0x00	trans_fifo_read Transmit FIFO Read. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, reading this register gives the data at the top of the transmit FIFO. Each consecutive read pops the transmit FIFO and gives the next data value that is currently at the top of the FIFO. When FIFOs are not implemented or not enabled, reading this register gives the data in the THR.

UART_RFW

Address: **Operational Base** + offset (0x0078)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9	WO	0x0	receive_fifo_framing_error Receive FIFO Framing Error. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, this bit is used to write framing error detection information to the receive FIFO. When FIFOs are not implemented or not enabled, this bit is used to write framing error detection information to the RBR.
8	WO	0x0	receive_fifo_parity_error Receive FIFO Parity Error. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, this bit is used to write parity error detection information to the receive FIFO. When FIFOs are not implemented or not enabled, this bit is used to write parity error detection information to the RBR.
7:0	WO	0x00	receive_fifo_write Receive FIFO Write Data. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, the data that is written to the RFWD is pushed into the receive FIFO. Each consecutive write pushes the new data to the next write location in the receive FIFO. When FIFOs are not implemented or not enabled, the data that is written to the RFWD is pushed into the RBR.

UART_USR

Address: **Operational Base** + offset (0x007C)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4	RO	0x0	receive_fifo_full Receive FIFO Full. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the receive FIFO is completely full. 1'b0: Receive FIFO not full 1'b1: Receive FIFO Full This bit is cleared when the RX FIFO is no longer full.
3	RO	0x0	receive_fifo_not_empty Receive FIFO Not Empty. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the receive FIFO contains one or more entries. 1'b0: Receive FIFO is empty 1'b1: Receive FIFO is not empty This bit is cleared when the RX FIFO is empty.

Rockchip Confidential

Bit	Attr	Reset Value	Description
2	RO	0x1	trasn_fifo_empty Transmit FIFO Empty. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the transmit FIFO is completely empty. 1'b0: Transmit FIFO is not empty 1'b1: Transmit FIFO is empty This bit is cleared when the TX FIFO is no longer empty.
1	RO	0x1	trans_fifo_not_full Transmit FIFO Not Full. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the transmit FIFO in not full. 1'b0: Transmit FIFO is full 1'b1: Transmit FIFO is not full This bit is cleared when the TX FIFO is full.
0	RO	0x0	uart_busy UART Busy. This is indicates that a serial transfer is in progress, when cleared indicates that the UART is idle or inactive. 1'b0: UART is idle or inactive 1'b1: UART is busy (actively transferring data) Note that it is possible for the UART Busy bit to be cleared even though a new character may have been sent from another device. That is, if the UART has no data in THR and RBR and there is no transmission in progress and a start bit of a new character has just reached the UART. This is due to the fact that a valid start is not seen until the middle of the bit period and this duration is dependent on the baud divisor that has been programmed. If a second system clock has been implemented (CLOCK_MODE == Enabled), the assertion of this bit is also delayed by several cycles of the slower clock.

UART_TFL

Address: **Operational Base** + offset (0x0080)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RO	0x00	trans_fifo_level Transmit FIFO Level. This is indicates the number of data entries in the transmit FIFO.

UART_RFL

Address: **Operational Base** + offset (0x0084)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RO	0x00	receive_fifo_level Receive FIFO Level. This is indicates the number of data entries in the receive FIFO.

UART_SRR

Address: **Operational Base** + offset (0x0088)

Bit	Attr	Reset Value	Description
31:3	RO	0x00000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
2	WO	0x0	xmit_fifo_reset XMIT FIFO Reset. This is a shadow register for the XMIT FIFO Reset bit (FCR[2]). This can be used to remove the burden on software having to store previously written FCR values (which are pretty static) just to reset the transmit FIFO. This resets the control portion of the transmit FIFO and treats the FIFO as empty. This also de-asserts the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit.
1	WO	0x0	rcvr_fifo_reset RCVR FIFO Reset. This is a shadow register for the RCVR FIFO Reset bit (FCR[1]). This can be used to remove the burden on software having to store previously written FCR values (which are pretty static) just to reset the receive FIFO This resets the control portion of the receive FIFO and treats the FIFO as empty. This also de-asserts the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit.
0	WO	0x0	uart_reset UART Reset. This asynchronously resets the UART and synchronously removes the reset assertion. For a two clock implementation both pclk and sclk domains are reset.

UART_SRTS

Address: **Operational Base** + offset (0x008C)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	shadow_req_to_send Shadow Request to Send. This is a shadow register for the RTS bit (MCR[1]), this can be used to remove the burden of having to performing a read-modify-write on the MCR. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] = 0), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] = 1), the rts_n output is held inactive-high while the value of this location is internally looped back to an input.

UART_SBCR

Address: **Operational Base** + offset (0x0090)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
0	RW	0x0	shadow_break_ctrl Shadow Break Control Bit. This is a shadow register for the Break bit (LCR[6]), this can be used to remove the burden of having to performing a read modify write on the LCR. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] = 1) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver.

UART_SDMAM

Address: **Operational Base** + offset (0x0094)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	shadow_dma_mode Shadow DMA Mode. This is a shadow register for the DMA mode bit (FCR[3]). This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the DMA Mode bit gets updated. This determines the DMA signalling mode used for the dma_tx_req_n and dma_rx_req_n output signals when additional DMA handshaking signals are not selected (DMA_EXTRA == NO). 1'b0: Mode 0 1'b1: Mode 1

UART_SFE

Address: **Operational Base** + offset (0x0098)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	shadow_fifo_en Shadow FIFO Enable. This is a shadow register for the FIFO enable bit (FCR[0]). This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the FIFO enable bit gets updated.This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. If this bit is set to zero (disabled) after being enabled then both the XMIT and RCVR controller portion of FIFOs are reset.

UART_SRT

Address: **Operational Base** + offset (0x009C)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1:0	RW	0x0	shadow_rcvr_trigger Shadow RCVR Trigger. This is a shadow register for the RCVR trigger bits (FCR[7:6]). This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the RCVR trigger bit gets updated. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt is generated. It also determines when the dma_rx_req_n signal is asserted when DMA Mode (FCR[3]) = 1. The following trigger levels are supported:

Rockchip Confidential

Bit	Attr	Reset Value	Description
			2'b00: 1 character in the FIFO 2'b01: FIFO 1/4 full 2'b10: FIFO 1/2 full 2'b11: FIFO 2 less than full

UART_STET

Address: **Operational Base** + offset (0x00A0)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1:0	RW	0x0	shadow_tx_empty_trigger Shadow TX Empty Trigger. This is a shadow register for the TX empty trigger bits (FCR[5:4]). This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the TX empty trigger bit gets updated. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. The following trigger levels are supported: 2'b00: FIFO empty 2'b01: 2 characters in the FIFO 2'b10: FIFO 1/4 full 2'b11: FIFO 1/2 full

UART_HTX

Address: **Operational Base** + offset (0x00A4)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	halt_tx_en This register is use to halt transmissions for testing, so that the transmit FIFO can be filled by the master when FIFOs are implemented and enabled. 1'b0: Halt TX disabled 1'b1: Halt TX enabled Note, if FIFOs are implemented and not enabled, the setting of the halt TX register has no effect on operation.

UART_DMASA

Address: **Operational Base** + offset (0x00A8)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	WO	0x0	dma_software_ack This register is use to perform a DMA software acknowledge if a transfer needs to be terminated due to an error condition. For example, if the DMA disables the channel, then the UART should clear its request. This causes the TX request, TX single, RX request and RX single signals to de-assert. Note that this bit is 'self-clearing'. It is not necessary to clear this bit.

UART_TCR

Address: **Operational Base** + offset (0x00AC)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
5	RW	0x0	auto_de Assert DE Automatically Enable. When data is written to the TXFIFO, the DE will automatically asserted, meanwhile, the RE will automatically de-asserted. 1'b0: Disable. 1'b1: Enable.
4	RW	0x0	re_pol Receiver Enable Polarity. 1'b0: re signal is active low. 1'b1: re signal is active high.
3	RW	0x0	de_pol Driver Enable Polarity. 1'b0: de signal is active high. 1'b1: de signal is active low.
2	RW	0x0	xfer_mode Transfer Mode. 1'b0: Hardware mode, DE and RE are mutually exclusive. By default 'de' and 're' will be disabled. User should programs the DE to active the 'de'. Once the TX FIFO becomes empty and the stop bit be sampled, 're' signal gets enabled and 'de' signal will be disabled, automatically. In this mode, hardware will consider the de-inactive timing and turn around timing (applied for 4 wire mode only), which are programmed in the DET and TAT register, respectively. When 'de' is valid, it is useless to configure RE, and vice versa. 1'b1: Software mode, transmit and receive can happen simultaneously. The user can enable DE, RE at any point of time. Turn around timing as programmed in the TAT register and de-inactive timing as programmed in the DET are not applicable in this mode.
1	RW	0x0	re_en Receiver Enable. 1'b0: RE signal disable, DE control both transmit and receive process. Correspondingly, assert DE for transmit state, while de-assert DE for receive state. In this scenario, RE-associated logics and TAT register will hold constant for lower power consumption. 1'b1: RE signal enable, DE control the transmit process, and RE control the receive process.
0	RW	0x0	rs485_en RS485 Enable. 1'b0: In this mode, the transfers are still in the RS232 mode. The registers of DE, RE, DET and TAT are reserved. 1'b1: In this mode, the transfers will happen in RS485 mode.

UART_DE

Address: **Operational Base** + offset (0x00B0)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	de The 'de' register bit is used to control assertion and de-assertion of 'de' signal. 1'b0: De-assert 'de' signal. 1'b1: Assert 'de' signal.

UART_RE

Address: **Operational Base** + offset (0x00B4)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	re The 're' register bit is used to control assertion and de-assertion of 're' signal. 1'b0: De-assert 're' signal. 1'b1: Assert 're' signal.

UART_DET

Address: **Operational Base** + offset (0x00B8)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	de_inact_time This field controls the amount of time (in terms of number of pclk periods) between the finish flag after the sampling point of the stop bit on the sout to the falling edge of Driver output enable signal. Note that, the mentioned finish flag, i.e. the actual starting effective point of the count, is located at the position of (DLL+1) sclk periods before the full stop bit ends, followed by 3~4 synchronization pclk periods. The actual time is the programmed value + 1.

UART_TAT

Address: **Operational Base** + offset (0x00BC)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	de2re_time Turn around time (in terms of pclk) for DE De-assertion to RE assertion. The actual time is the programmed value + 1.

UART_CPR

Address: **Operational Base** + offset (0x00F4)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RO	0x04	fifo_mode 8'h4 means FIFO mode is 64.
15:14	RO	0x0	reserved
13	RO	0x1	dma_extra 1'b1 means DMA_EXTRA enabled.
12	RO	0x1	uart_add_encoded_params 1'b1 means UART_ADD_ENCODED_PARAMS enabled.
11	RO	0x1	shadow 1'b1 means SHADOW mode enabled.
10	RO	0x1	fifo_stat 1'b1 means FIFO_STAT enabled.
9	RO	0x1	fifo_access 1'b1 means FIFO ACCESS enabled.
8	RO	0x1	new_feat 1'b1 means Additional features enabled.
7	RO	0x1	sir_lp_mode 1'b1 means SIR_LP mode enabled.
6	RO	0x1	sir_mode 1'b1 means SIR mode enabled.
5	RO	0x1	thre_mode 1'b1 means THRE mode enabled.

Rockchip Confidential

Bit	Attr	Reset Value	Description
4	RO	0x1	afce_mode 1'b1 means AFCE mode enabled.
3:2	RO	0x0	reserved
1:0	RO	0x2	apb_data_width 2'b10 means APB data width is 32bit.

UART_UCV

Address: **Operational Base** + offset (0x00F8)

Bit	Attr	Reset Value	Description
31:0	RO	0x3430322a	ver ASCII value for each number in the version.

UART_CTR

Address: **Operational Base** + offset (0x00FC)

Bit	Attr	Reset Value	Description
31:0	RO	0x44570110	peripheral_id This register contains the peripherals identification code.

33.6 Application Notes

33.6.1 No FIFO Mode Transfer Flow

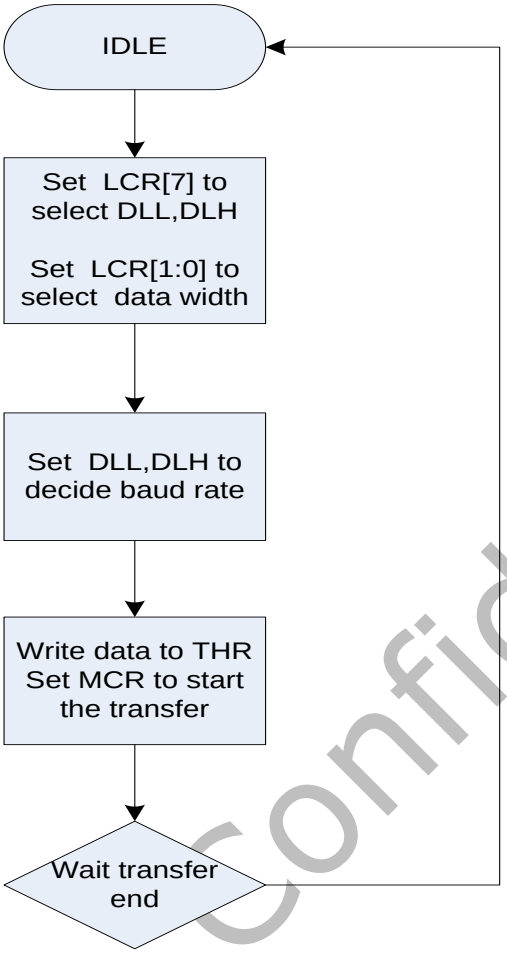

Fig. 33-7 UART None FIFO Mode

33.6.2 FIFO Mode Transfer Flow

Rockchip Confidential

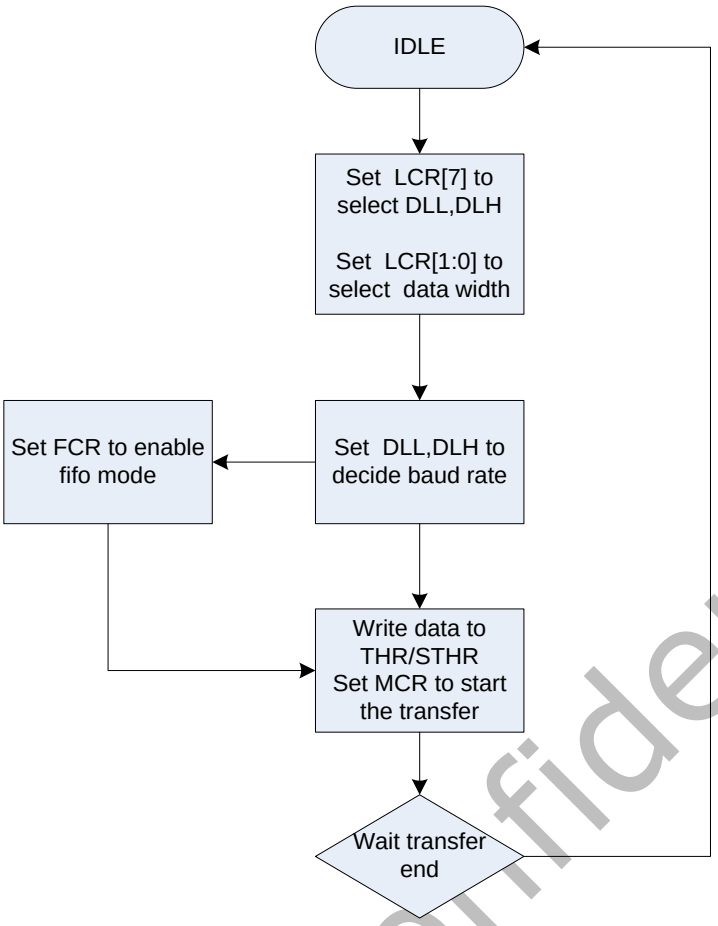

Fig. 33-8 UART FIFO Mode

The UART is an APB slave performing:
Serial-to-parallel conversion on data received from a peripheral device. Parallel-to-serial conversion on data transmitted to the peripheral device. The CPU reads and writes data and control/status information through the APB interface. The transmitting and receiving paths are buffered with internal FIFO memories enabling up to 64-bytes to be stored independently in both transmit and receive modes. A baud rate generator can generate a common transmit and receive internal clock input. The baud rates will depend on the internal clock frequency. The UART will also provide transmit, receive and exception interrupts to system. A DMA interface is implemented for improving the system performance.

33.6.3 Baud Rate Calculation

UART clock generation

UARTs source clocks (SCLK) can be selected from different PLL outputs, or from XIN24M. SCLK can be divided to different frequency, please refer to CRU chapter.

UART baud rate configuration

The following table provides some reference configuration for different UART baud rates.

Table 33-7 UART Baud Rate Configuration

Baud Rate	Reference Configuration
115.2 Kbps	Configure PLL to get 1188MHz clock output; Divide 1188MHz clock by 1536/24750 to get 73.728MHz clock by shared fractional divider; Divide 73.728MHz clock by 20 to get 3.6864MHz clock by independent integer divider; Configure UART_DLL to 2.
460.8 Kbps	Configure PLL to get 1188MHz clock output; Divide 1188MHz clock by 1536/24750 to get 73.728MHz clock by shared fractional divider; Divide 73.728MHz clock by 10 to get 460.8KHz clock by independent integer divider; Configure UART_DLL to 1.

Rockchip Confidential

921.6 Kbps	Configure PLL to get 1188MHz clock output; Divide 1188MHz clock by 1536/24750 to get 73.728MHz clock by shared fractional divider; Divide 73.728MHz clock by 5 to get 921.6KHz clock by independent integer divider; Configure UART_DLL to 1.
1.5 Mbps	Configure PLL to get 800MHz clock output; Divide 1000MHz clock by 24/100 to get 192MHz clock by shared fractional divider; Divide 192MHz clock by 8 to get 24MHz clock by independent integer divider; Configure UART_DLL to 1.
3 Mbps	Configure PLL to get 800MHz clock output; Divide 1000MHz clock by 24/100 to get 192MHz clock by shared fractional divider; Divide 192MHz clock by 4 to get 48MHz clock by independent integer divider; Configure UART_DLL to 1.
4 Mbps	Configure PLL to get 800MHz clock output; Divide 1000MHz clock by 24/100 to get 192MHz clock by shared fractional divider; Divide 192MHz clock by 3 to get 64MHz clock by independent integer divider; Configure UART_DLL to 1.
8 Mbps	Configure PLL to get 800MHz clock output; Divide 800MHz clock by 16/100 to get 128MHz clock by shared fractional divider; Divide 128MHz clock by 1 to get 128MHz clock by independent integer divider; Configure UART_DLL to 1.

Chapter 34 Controller Area Network (CAN)

34.1 Overview

CAN (Rockchip Controller Area Network) bus is a robust vehicle bus standard designed to allow microcontrollers and devices to communicate with each other in applications without a host computer. It is a message-based protocol, designed originally for multiplex electrical wiring within automobiles to save on copper, but is also used in many other contexts.
RKCAN controller supports the following features:

- Support CAN and CANFD protocol
- Support AHB slave interface
- Not support AHB master interface
- Support classical and can-fd transmit or receive standard frame
- Support classical and can-fd transmit or receive extended frame
- Support transmit or receive data frame, remote frame, overload frame, error frame and frame interval
- Support transmit or receive error count
- Support acceptance filter
- Support bit error, bit stuffing error, form error, ack error and crc error
- Support interrupt and all interrupt can be masked
- Support controller status query
- Support error code check
- Support self test mode
- Support single sample and three sample configurable
- Support SJW(reSynchronization Jump Width) configurable
- Support BRP(system prescaler coefficient) configurable
- Support bit timing configurable
- Support loop-back mode for self-test operation
- Support silent mode for debug
- Support auto retransmission mode
- Support auto bus on after bus-off state
- Support 2 transmit buffers
- Support Internal Storage Mode
- Support protocol exception event
- Support DMA

34.2 Function Description

The features listed below which may or may not be present in actual product, may be subject to the third party licensing requirements. Please contact Rockchip for actual product feature configurations and licensing requirements.

34.2.1 Block Diagram

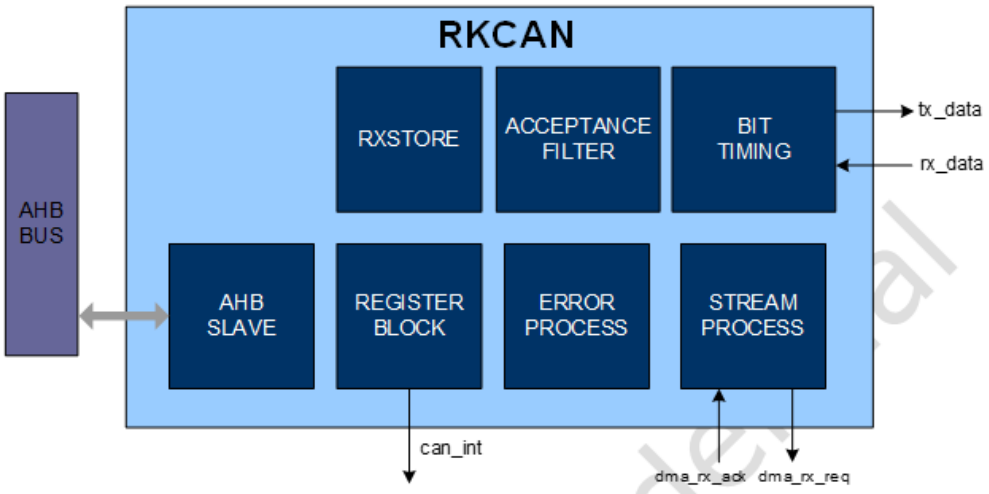

Fig. 34-1 RKCAN Controller Block Diagram

Rockchip Confidential

This version of RKCAN controller includes the previous version of CAN logic in compliance with old software application and also includes new CANFD logic which support transmitting and receiving both CAN and CANFD frame.

34.2.2 ACCEPTANCE FILTER

The Acceptance Filter (ATF) is a receive filter module. RKCAN can filter the received CAN frames based on four identifiers: ID, RTR, and DLC. There are five sets of ID_RTR registers and one set of DLC registers for configuring the filter mode of RKCAN.The filtering mode based on ID and RTR has two types: List Mode and Mask Mode. The current ATF Mask register can be configured as either a mask mode or a list mode through the ATFMn.mask bit.

(1) Mask Mode: ATFM is used as the mask register of ATF, and RKCAN provides five sets of configurable 'filter-mask' registers.

(2) List Mode: ATFM is used as the filter register, and RKCAN provides ten configurable 'filter' registers."

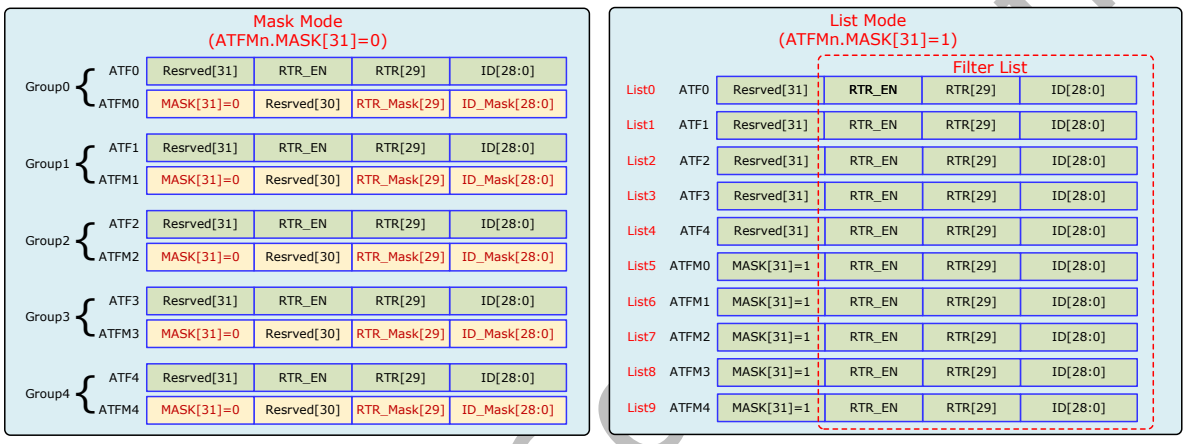

Fig. 34-2 ATF Mode

When filtering based on DLC, there are also two modes: Over Mode and Less Mode. The ATF_DLC.en bit is used to enable the DLC filter, the ARF_DLC.mode bit is used to select between the two modes, and the ATF_DLC.dlc[3:0] is used to configure the filter threshold.

(1) Over Mode: When ARF_DLC.mode is 0, if the dlc value of the received CAN frame is greater than or equal to ATF_DLC.dlc[3:0], the CAN frame can be received by RKCAN and stored in memory.

(2) Less Mode: When ARF_DLC.mode is 1, if the dlc value of the received CAN frame is less than or equal to ATF_DLC.dlc[3:0], the CAN frame can be received by RKCAN and stored in memory.

ATF_CTL[9:0] is used to control the switch status of ATF0~4 and ATFM0~4.

34.2.3 BIT TIMING

34.2.3.1 Bit Timing Logic

The CAN FD protocol defines two bit rates, the first for the ARBITRATION-PHASE with a longer bit time and the second for the data phase with the same or with a shorter bit time. The definition for the first bit rate is the same as for the NOMINAL BIT RATE and the NOMINAL BIT TIME in the CAN protocol specification. The definition for the second bit rate, the DATA BIT RATE WITH the DATA BIT TIME, requires a separate configuration register set.

The bit timing logic controls the sampling point position through the buffer bits in the timing register to ensure the accuracy of the data sampling. The bit timing logic receives the clock frequency division signal for identification, sets the bus timing parameters, establishes synchronization parameters, and adjusts the bus transmission rate. At the same time, the bus is monitored and the message to be sent is transmitted to the bus at the set timing.

According to the provisions of the CAN protocol: the CAN bus is always at a high level when no message is sent, and the continuous recessive bit is monitored on the bus. At this time,

Rockchip Confidential

the bus is in an idle state, and the arbitration priority is low, ready to receive data at any time. When the bus detects a transition from a recessive bit to a dominant bit, it is proved that the frame start bit starts transmitting, and the bus performs a hard synchronization in the bit start sync segment. Then, in the process of receiving the message, once the edge of the transition close to the sampling point is detected and the edge of the edge and the synchronization segment have a phase error lower than the synchronization width (SJW is taken when the value exceeds SJW), the controller executes once resynchronization, resynchronization can be performed multiple times during one data transmission.

34.2.3.2 Bit Timing Definition

The transmission time of each bit is divided into 4 parts:

$$t_{nbt} = t_{sync_seg} + t_{prop_seg} + t_{phase_seg1} + t_{phase_seg2}$$

t_{sync_seg}, t_{prop_seg}, t_{phase_seg1} and t_{phase_seg2} are integer multiples of the unit time(t_{sclk}), and this unit time is a specific multiple of the system clock, which is determined by the division factor BRP in the bus timing register: 1. The counter is obtained by the BRP operation; 2. The system clock clk is counted by the counter; 3. When the limit is reached, a clock with a period of t_{sclk} is generated.

In the system design, considering the cyclical occurrence of each time period, a state machine with three states is used in the bit timing design. The three states correspond to the sync segment(sync_seg) and the phase buffer segment 1 (phase_seg1=phase_seg1+prog_seg) and the phase buffer segment 2 (phase_seg2), respectively. Where PHASE_SEG1 range: 1~16; PHASE_SEG2 range: 1~8; BRP range: 1~64.

$$t_{sync_seg} = 1 \times t_{sclk}$$

$$t_{prop_seg} + t_{phase_seg1} = t_{sclk} \times (8 \times TSEG1.3 + 4 \times TSEG1.2 + 2 \times TSEG1.1 + TSEG1.0 + 1)$$

$$t_{phase_seg2} = t_{sclk} \times (4 \times TSEG2.2 + 2 \times TSEG2.1 + TSEG1.0 + 1)$$

Define a counter to count t_{sclk}. When the count reaches the TSEG1, TSEG2 defined in the bus timing register and the length of the synchronization segment defined in the design, the system will generate the corresponding transition conditions: go_seg1, go_seg2, go_sync.

By judging these transition conditions, the control state machine cycles through the above three states.

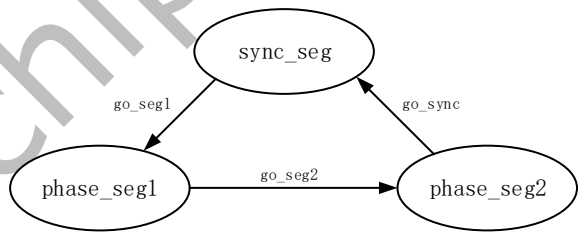

Fig. 34-3 Bit timing FSM

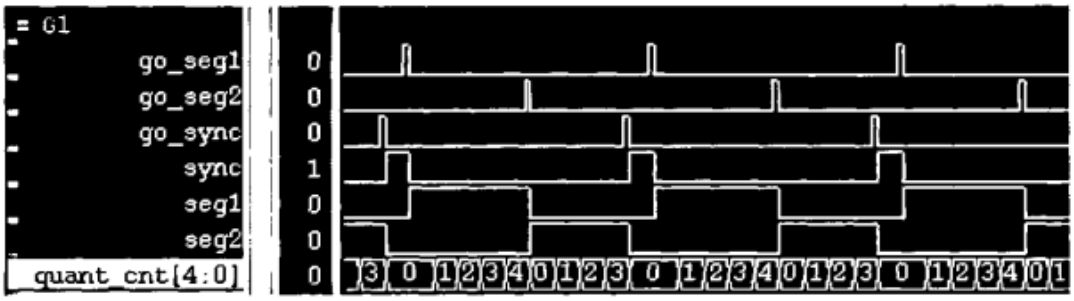

Fig. 34-4 Bit timing waveform diagram

34.2.3.3 Bit time transition

The first part of a CAN FD frame, until the BRS bit, is transmitted with the NOMINAL BIT RATE. The bit rate is switched if the BRS bit is recessive, until the CRC DELIMITER is reached or until the CAN FD controller sees an error condition that results in the starting

Rockchip Confidential

of an ERROR FRAME. CAN FD ERROR FRAMES, as well as ACK FIELD, END OF FRAME, OVERLOAD FRAMES, and all frames in CAN format are transmitted with the NOMINAL BIT RATE.

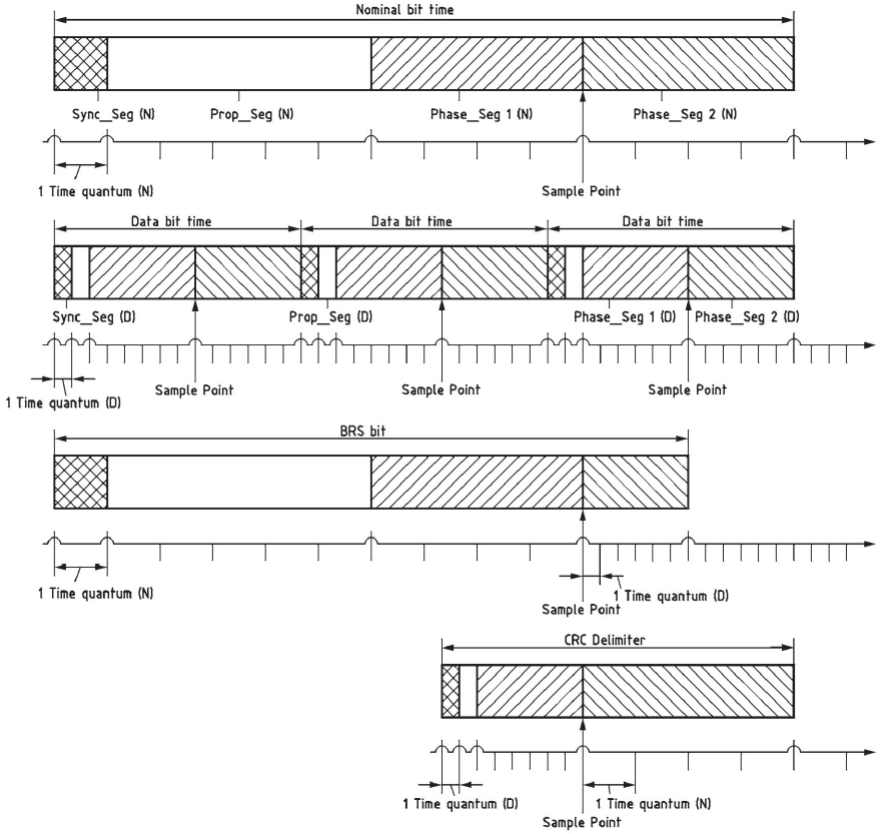

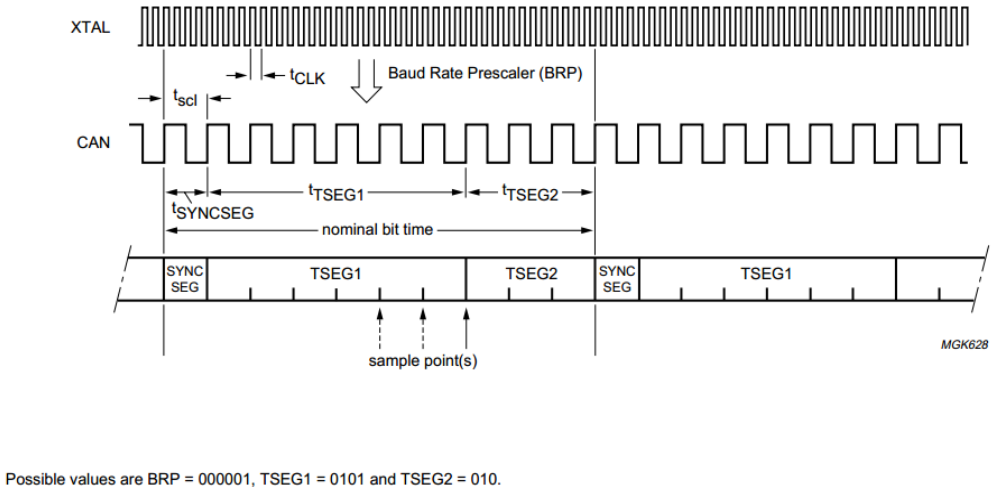

Fig. 34-5 Bit Timing

34.2.3.4 Sampling Point and Sending Point

Sampling Point: According to the agreement, the sample point sample_point should be between phase_seg1 and phase_seg2. It is designed to be in the position of phase_seg2 synchronization. The sampling pulse width is defined as one system clock cycle. Considering the accuracy of sampling, you can use the method of taking three samples to take the mean. The interval between each sample point is one t_{sclk}.

Possible values are BRP = 000001, TSEG1 = 0101 and TSEG2 = 010.

Fig. 34-6 Three sampling diagram

Sending Point: The location of the transmission point(tx_point) should be at the beginning of each bit time according to the protocol, and it is designed to synchronize it with the go_sync signal. In addition, if it is in sync or resynchronize, tx_point will be valid immediately.

Rockchip Confidential

34.2.3.5 Bit Synchronization

With the synchronization method, one or more nodes that satisfy the synchronization condition align their synchronization segments with the transmission data on the bus at a specific time. Synchronization occurs on the 1-to-0 transition edge in order to control the distance from the transition edge to the sample point. Two synchronization methods are defined in the CAN bus communication protocol: hard synchronization and resynchronization.

Hard_sync: All nodes must be synchronized to the leading edge of the starting frame of the node that first started transmitting the message. At the beginning of each frame of data, a synchronization action is taken between the nodes.

Hard synchronization implementation method: determine whether the bus state meets the frame start condition specified in the protocol, and the node is not in the state of the data to be transmitted. At this time, a hard synchronization flag signal hard_sync is generated, and the pulse width is a system clock; The hard_sync entry is added to the control condition of the go_seg1 signal, and go_seg1 is valid immediately when the hard_sync signal is '1'. Therefore, once the hard synchronization condition is met, the system enters the phase_seg1 segment, thereby achieving synchronization.

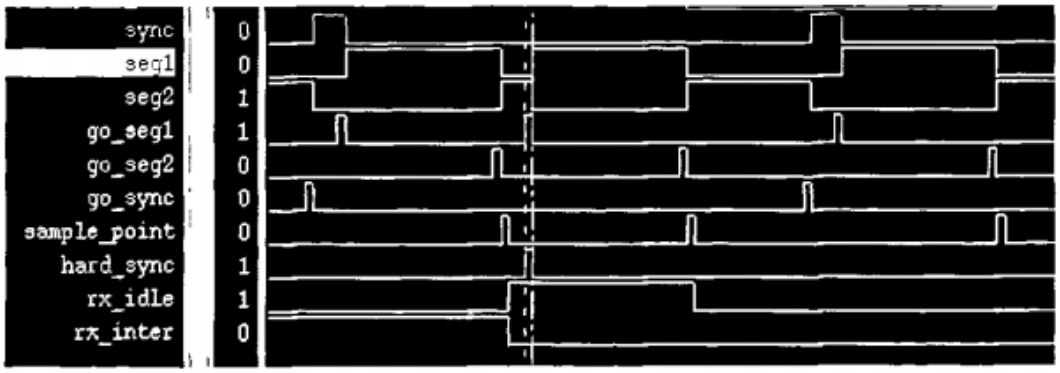

Fig. 34-7 Hard_sync waveform diagram

Resynchronization: In addition to generating hard synchronization at the beginning of each frame of data, the CAN bus communication protocol also specifies the transmission of data for each frame. When the timing coordination between the nodes is not ideal, it will be resynchronized, so that the cooperation between the nodes is in a good state.

For the receiver, the bus changes it received should occur in the sync segment. Once the receiver's status violates this rule, the receiver will perform a resynchronization.

Two situations that require resynchronization:

1. The jump of the bus value '1' to '0' occurs between the sync segment and the sample point, which is a delay jump;
2. The jump of the bus value '1' to '0' occurs between the sample point and the sync segment, which is an early jump.

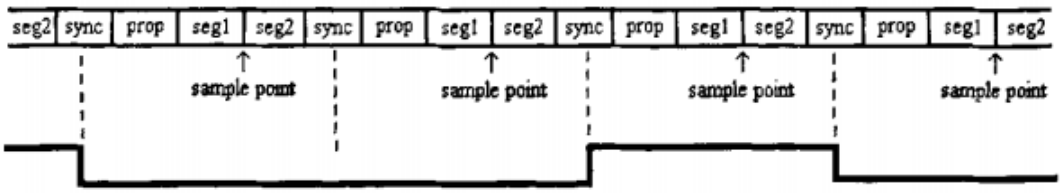

Fig. 34-8 Resynchronization

Resynchronization method:

1. Condition for resynchronization: the receiver is in a mode of receiving data (not inter-frame space or bus idle), and a resynchronization flag signal ‘resync’ is generated when a jump of the bus value '1' to '0' occurs;
2. According to the position of the resynchronization flag signal, it is determined that the abnormal jump is a delay jump or an early jump;
3. Counting the delay or the length of the advance by the counter;
4. In this bit, phase_seg1 is added with a delay time or phase_seg2 is subtracted from the advance time to obtain a new phase buffer time for the bit, thereby achieving synchronization.

Rockchip Confidential

34.2.3.6 Transmitter Delay Compensation

During the data phase of a CAN FD transmission, only one node is transmitting; all others are receiving. Therefore, the propagation delay does not limit the maximum data rate. When transmitting via pin, TXCAN, the CAN FD Controller module receives the transmitted data from its local CAN transceiver via pin, RXCAN. The received data are delayed by the CAN
transceiver's loop delay. In case this delay is greater than 1 + DTSEG1, a bit error will be detected.
In order to enable a data phase bit time that is shorter than the transceiver loop delay, the Transmitter Delay Compensation (TDC) is implemented. Instead of sampling after DTSEG1, a
Secondary Sample Point (SSP) is calculated and used for sampling during the data phase of a
CAN FD message.

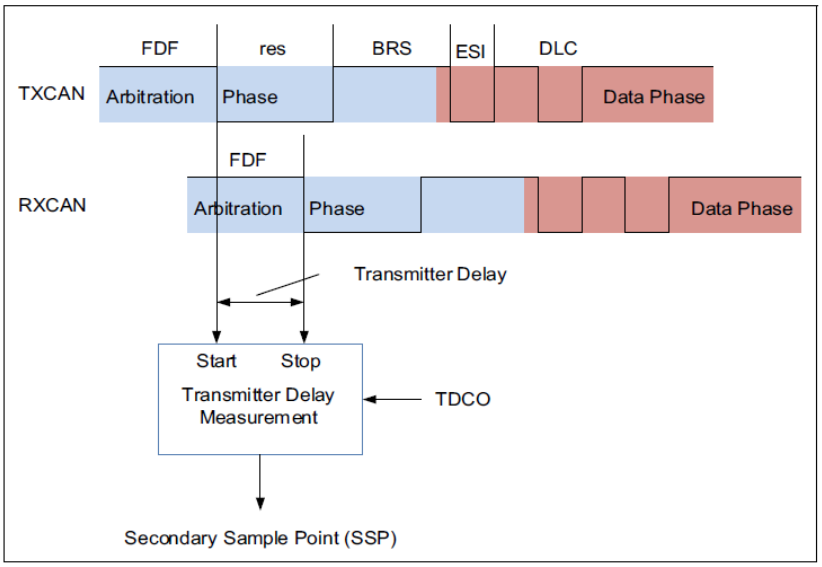

Fig. 34-9 Measurement of Transceiver Delay

34.2.4 RXSTORE

34.2.4.1 Internal Storage Mode

To store the frame data received by RKCAN only in the internal SRAM, the STR_CTL.stm needs to be configured as 0. The frame data received by RKCAN will only be stored in the internal SRAM. The size of the internal SRAM is 256x32bit. The CPU can query the remaining amount of data in the internal SRAM through the STR_STAT.intm_left_cnt register. After the CPU reads the data, the STR_STAT.intm_left_cnt will decrease accordingly. At the same time, the way the internal SRAM stores data can be divided into four data storage formats: Flexible, CAN Fixed, CANFD Fixed, and Mixed. Use STR_CTL_ism_sel[1:0] to select among the four formats, the specific explanations are as follows:

(1) Flexible: The data of each frame is seamlessly stored in the SRAM according to its volume.

(2) CAN Fixed: A fixed 4 words are used to store a frame of data.

(3) CANFD Fixed: A fixed 18 words are used to store a frame of data.

(4) Mixed: CAN frames use 4 words to store a frame of data, and CANFD frames use 18 words to store a frame of data. It should be noted that when the external storage mode is turned on, the internal SRAM will still be used for data caching, and the STR_CTL_ism_sel[1:0] can still be used to select the format of the data cached in the internal SRAM, but the external memory uses a fixed 18

Rockchip Confidential

words to store a frame of data.

34.2.4.2 External Storage Mode

To store the frame data received by RKCAN in external memory (DDR or System Memory), the STORE_CTL.stm needs to be configured as 1, and registers such as TXTHR, START_ADDR, and EXTM_SIZE need to be configured. RKCAN will first store the received frame data in the internal SRAM. When the amount of data received by RKCAN exceeds the threshold set by TXTHR, it will automatically write the data stored in the internal SRAM to the external memory through AHB Master, and update the WADDR register to the tail address of the part of the external memory that has been written with data. At the same time, it updates the status of the two empty/full flags STR_STAT.extm_empty and STR_STAT.extm_full. RKCAN sends an interrupt to the CPU. The CPU can determine the amount of data that can be read by querying the value of the WADDR register. After the CPU completes the frame data reading, it needs to write the latest CPU_RD_ADDR value into the RADDR register of RKCAN. RKCAN will calculate the empty/full status of the memory based on the values of the RADDR and WADDR registers. The CPU can query the amount of data in the external memory through STR_STAT.extm_left_cnt, and query the remaining amount of data in the internal SRAM through STR_STAT.intm_left_cnt.

This feature is currently only used for debugging. For specific application details, please consult Rockchip.

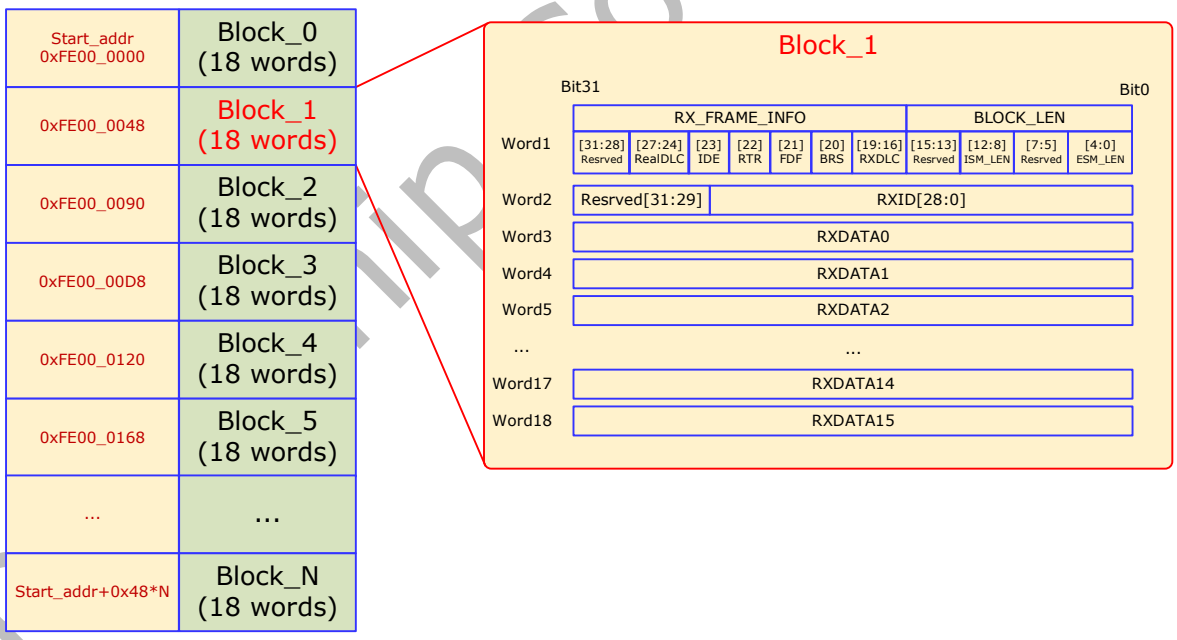

Fig. 34-10 Data storage format under external storage mode

34.2.4.3 ESM Timeout Mechanism

RKCAN also has a timeout mechanism to prevent the RKCAN receive buffer from overflowing when the CPU does not read data for a long time. The timeout threshold is configured through the BUF_TIMEOUT register. In internal storage mode, if the CPU does not read the data in the internal SRAM for a long time, a timeout interrupt will occur; in external storage mode, if the CPU does not update the value of the CPU_RD_ADDR register for a long time, a timeout interrupt will occur. The same interrupt flag is used in both modes.

Rockchip Confidential

34.2.5 ERROR PROCESS

There are five types of errors. Multiple errors can occur at the same time.

- **BIT ERROR**:
  A unit that is sending a bit on the bus also monitors the bus. A BIT ERROR has to be detected at that bit time, when the bit value that is monitored is different form the bit value that is sent. An exception is the sending of a 'recessive' bit during the stuffed bit stream of the ARBITRATION FIELD of during the ACK SLOT. Then no BIT ERROR occurs when a 'dominant' bit is monitored. A TRANSMITTER sending a PASSIVE ERROR FLAG and detecting a 'dominant' bit does not interpret this as a BIT ERROR.
- **BIT STUFF ERROR**:
  A STUFF ERROR has to be detected at the bit time of the 6^{th} consecutive equal bit level in a message field that should be coded by the method of bit stuffing.
- **FORM ERROR**:
  A FORM ERROR has to be detected when a fixed-form bit field contains one or more illegal bits. (Exception is the detection of a dominant bit during the last bit of END OF FRAME by a RECEIVER, or the detection of a dominant bit during the last bit of ERROR DELIMITER or OVERLOAD DELIMITER by any node). When the value of a fixed STUFF-BIT in the CAN FD format CRC SEQUENCE is equal to its preceding bit, this shall also be detected as a FORM-ERROR.
- **ACK ERROR**:
  An ACK ERROR has to be detected by a transmitter whenever it does not monitor a 'dominant' bit during the ACK SLOT.
- **CRC ERROR**:
  The CRC sequence consists of the result of the CRC calculation by the transmitter. The receivers calculate the CRC in the same way as the transmitter. A CRC ERROR has to be detected, if the calculated result is not the same as that received in the CRC sequence.

34.3 Register Description

34.3.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows. address can be divided into different length for different usage, which is shown as follows.

11	RW	0x0	crcerr_ack_mode 1'b0: Not send ACK when CRC Error detected 1'b1: Send ACK when CRC Error detected
10	RW	0x0	pass_err_mode 1'b0: PASSIVE Error Flag use recessive bits 1'b1: PASSIVE Error Flag use dominant bits
9	RW	0x0	dis_pee Disable Protocol Exception Event Detection/Generation 1'b0: PEE detection/generation is enabled. If the CANFD receiver detects the res bit as 1, it goes to Bus Integration state (PEE_config) and waits for Bus Idle condition (11 consecutive nominal recessive bits). The error counter remains unchanged. 1'b1: Disable Protocol Exception Event detection/generation by CANFD receiver if "res" bit in CANFD frame is detected as 1. In this case, CANFD receiver generates Form error.
8	RW	0x0	rett_mode Restricted Operation Mode In Restricted Operation Mode, RKCAN is able to transmit and to receive DATA FRAMES and REMOTE FRAMES and it gives ACKNOWLEDGE to valid frames, but it does not send ACTIVE ERROR FRAMES or OVERLOAD FRAMES. The error counters are not incremented or decremented. 1'b0: Disable 1'b1: Enable
7	RW	0x0	auto_bus_on Auto Bus On Enable 1'b0: After the RKCAN has entered bus_off state, the software can start a bus_off_recovery sequence by resetting the work_mode to 0. 1'b1: Automatic reset TEC/REC to bus_on after 128 occurrence of 11 consecutive recessive bits have been monitored on the bus.
6	RO	0x0	reserved
5	RW	0x0	rxstx_mode Receive Self Transmit data mode 1'b0: Disable 1'b1: Enable. When the RKCAN sends data, it can also receive the data sent by itself.
4	RW	0x0	lback_mode Loopback Mode 1'b0: Disable 1'b1: Enable
3	RW	0x0	silent_mode Silent Mode 1'b0: Disable 1'b1: Enable

Rockchip Confidential

Bit	Attr	Reset Value	Description
2	RW	0x0	self_test Reserved Self check ACK slot when TX frame Using ERROR_MASK[4]can achieve the same function When in self_test mode, the receiver does not need to return an ACK signal when receiving data. Therefore, no error ack will occur in self_test mode. When in 'lback_mode' or 'silent_mode', it needs to enable 'self_test' mode when sending frame.
1	RW	0x0	sleep_mode Sleep Mode This is the Sleep mode request bit 1'b0: No such request 1'b1: Request core to be in Sleep mode This bit is cleared when the core wakes up from Sleep mode.
0	RW	0x0	work_mode Work Mode 1'b0: Idle mode, CAN stop transmit and registers can be configured 1'b1: Work mode, CAN enter the working mode, Receive/transmit data

RKCAN_CMD

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	R/WSC	0x0	tx1_req Transmit request enable 1'b0: Disable 1'b1: Enable When 'tx1_req' is enable, the RKCAN buffer1 is in the transmit mode and cannot receive frames from other CANs. When the RKCAN buffer1 transmission frame complete, 'tx1_req' is automatically cleared to 0. Also, when RKCAN is set 'work_mode' to 'reset_mode', tx_req' is cleared to 0.
0	R/WSC	0x0	tx0_req Transmit request enable 1'b0: Disable 1'b1: Enable When 'tx0_req' is enable, the RKCAN buffer0 is in the transmit mode and cannot receive frames from other CANs. When the RKCAN buffer0 transmission frame complete, 'tx0_req' is automatically cleared to 0. Also, when RKCAN is set 'work_mode' to 'reset_mode', tx_req' is cleared to 0.

34.4 Interface Description

Table 34-1 CAN IO Interface Description

Module Pin	Direction	Rockchip Matrix IO	IOMUX Setting
CAN0 TX	I/O	RM_IO	
CAN0 RX	I/O	RM_IO	
CAN1 TX	I/O	RM_IO	
CAN1 RX	I/O	RM_IO	

Notes: I=input, O=output, I/O=input/output. For the configuration of RM_IO, please refer to chapter "Rockchip Matrix IO".

34.5 Application Notes

34.5.1 Controller initialization flow

The controller must configure the registers after power-up or hardware reset. During the operation of the controller, a software reset request may be sent and reconfigured (re-initialized) as shown below.

After the initialization is completed, the controller enters the working mode, sends the frame to be sent to the buffer, and then sets the "send request" flag of the command register to start transmitting.

Rockchip Confidential

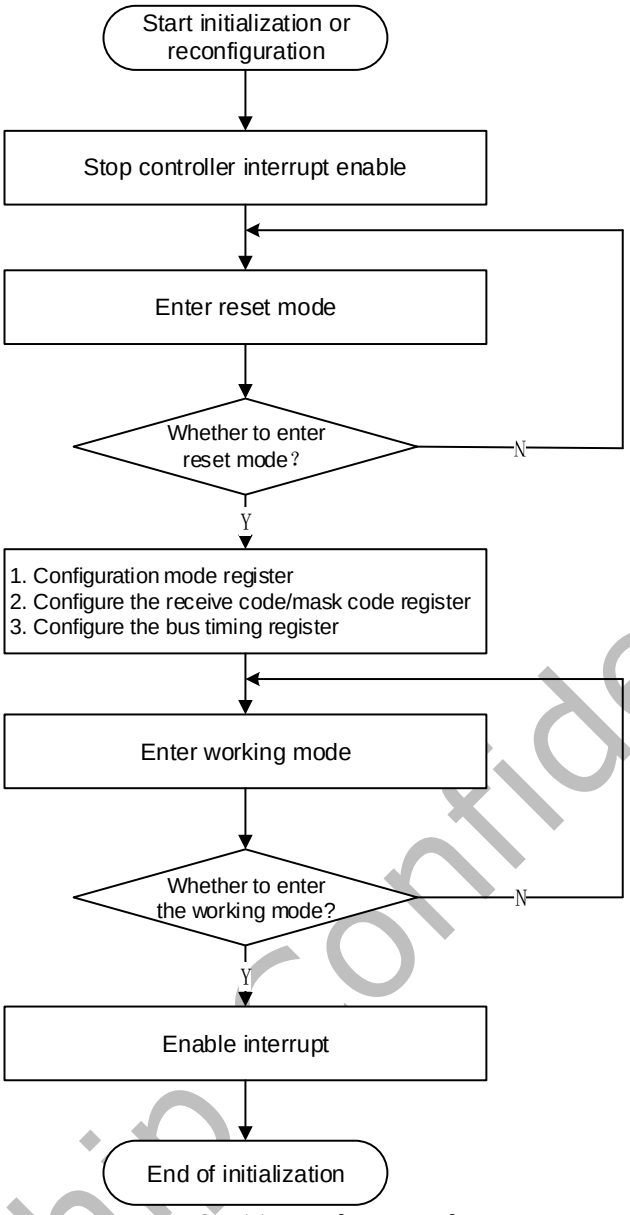

Fig. 34-11 Initialization Flow

34.5.2 Loop-back Mode

The controller must configure the registers after power-up or hardware reset. During the operation of the controller, a software reset request may be sent and reconfigured (re-initialized) as shown below.

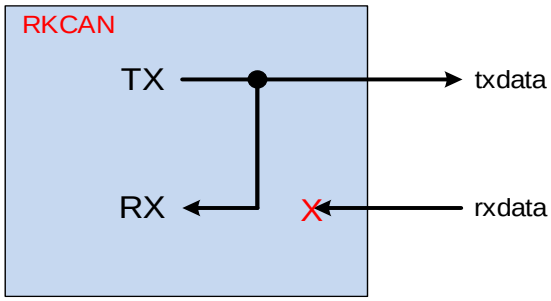

Fig. 34-12 Loop-back Mode

34.5.3 Silent Mode

The controller must configure the registers after power-up or hardware reset. During the operation of the controller, a software reset request may be sent and reconfigured (re-initialized) as shown below.

Rockchip Confidential

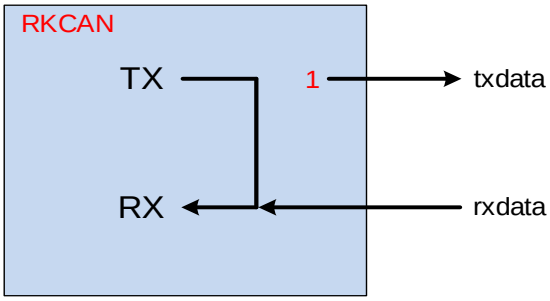

Fig. 34-13 Silent Mode

34.5.4 RXSTX Mode

(1)rxstx_mode=0, RKCAN cannot receive the data sent by itself;
(2)rxstx_mode=1, RKCAN can receive the data sent by itself, and when the ID of the frame is the same as the ID_CODE of RKCAN itself, RKCAN will store the frame information into RX storage.

34.5.5 Auto Retx Mode

RKCAN supports two automatic retransmission modes:

(1) Unlimited Retransmission Mode: There is no limit to the number of retransmissions until the retransmission is successful.

(2) Limited Retransmissions Mode: The threshold for the number of automatic retransmissions can be configured. If the limit threshold is reached and the retransmission is still not successful, the retransmission will stop, and a retransmission failure interrupt will be issued. RKCAN will also count the reasons and corresponding times that cause the transmission failure during the retransmission process, such as arbitration failure, NoACK, or bus error, etc.

34.5.6 Bus Off Recovery Mechanism

RKCAN supports three configurable Bus_off recovery mechanisms, which are:

(1) Automatic Recovery: When the RKCAN node detects 11 recessive bits (no active messages on the CAN bus) appearing consecutively 128 times, it can automatically exit the Bus_off state.

(2) Timed Recovery: The timing length can be set by configuring the register. After the timer expires, RKCAN exits the Bus_off state. The software can implement fast recovery and slow recovery functions using the timed recovery mode.

(3) Manual Recovery: In manual recovery mode, RKCAN will not automatically exit the Bus-off state. It can only exit the Bus-off state by configuring the manual recovery register.

34.5.7 Sleep Mode

After enabling Sleep Mode, RKCAN will automatically enter a low-power mode when the bus is idle, turning off the internal clock. The internal clock will automatically turn on when there is a data frame on the bus or when a data frame needs to be sent.

34.5.8 Multi-frame Mode

RKCAN supports an interrupt being issued upon receiving each frame, and it can also be configured to issue an interrupt only after receiving N frames in multi-frame mode. This can reduce the number of interrupts and reduce software intervention. The related configuration can be found in the register RXINT_CTRL register and RXINT_TIMEOUT.

Chapter 35 Master Double Data Rate Serial Memory Controller (MASTER DSMC)

35.1 Overview

The DSMC module provides function and operation for interfacing to the DSMC memory devices, and the Rockchip LocalBus devices. The DSMC achieves high speed read/write throughput by double data rate interface.

The main feature is shown below.

- Support the double data rate interface
- Support up to select 4 chips
- Support 8-wire and 16-wire serial transfer mode
- Support configurable write/read contiguous address merging transaction
- Support configurable write/read boundary address splitting transaction
- Support to transform WRAP transfer to INCR transfer
- Support byte access
- Support configurable DQS input clock delay line
- For LocalBus devices, support to assert the selecting signals CS simultaneously in the write transaction
- For LocalBus devices, support 3 clock mode : normal mode, always-on mode, no-edge-clk mode
- For LocalBus devices, support to request DMAC to transfer data when receiving interrupt 0/1
- For LocalBus devices, support configurable serial address width: 16 bits or 32 bits in different region

35.2 Block Diagram

DSMC is comprised of:

- APB Interface

The APB Interface implements the APB slave operation. Its data bus width is 32 bits.

- AXI Interface

The AXI Interface is a XIP interface to access internal device. Its data bus width is 64 bits.

- I/O Port Interface

External data interface to or from I/O pads.

- Core

The core module is used to control the data stream of TX/RX datapath.

Rockchip Confidential

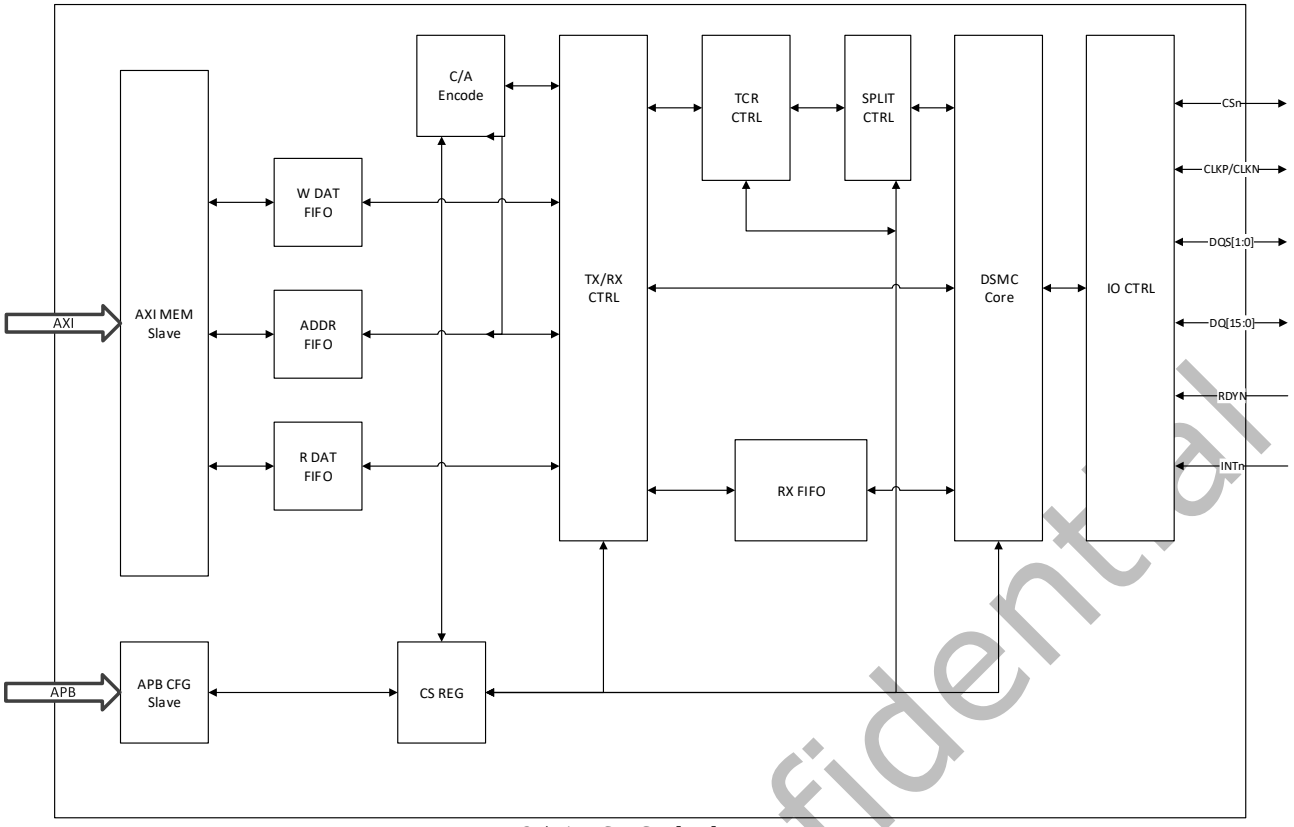

Fig. 35-1 DSMC Block Diagram

35.3 Function Description

The DSMC module is high throughput memory interface. It provides execute in place (XIP) and block copy access to DSMC memory devices (HyperRAM and HyperFlash). The DSMC module is compliant to the Cypress DSMC™ Specification. Meanwhile, it could access Rockchip LocalBus devices, and transfer instructions or bulk data with high speed.

35.3.1 DSMC Core

This section describes physical interface of DSMC module. The DSMC core generates DSMC timing from control signals.

35.3.1.1 Read

DSMC Core module asserts CSn, CLKP/CLKN, and DQ. Then, it outputs 3 words command/address, and reads 1 or more data by the timing of DQS. The DSMC Core puts the transaction request from AXI bus, such as the burst type and the burst length, to the C/A cycle on DSMC as is shown below.

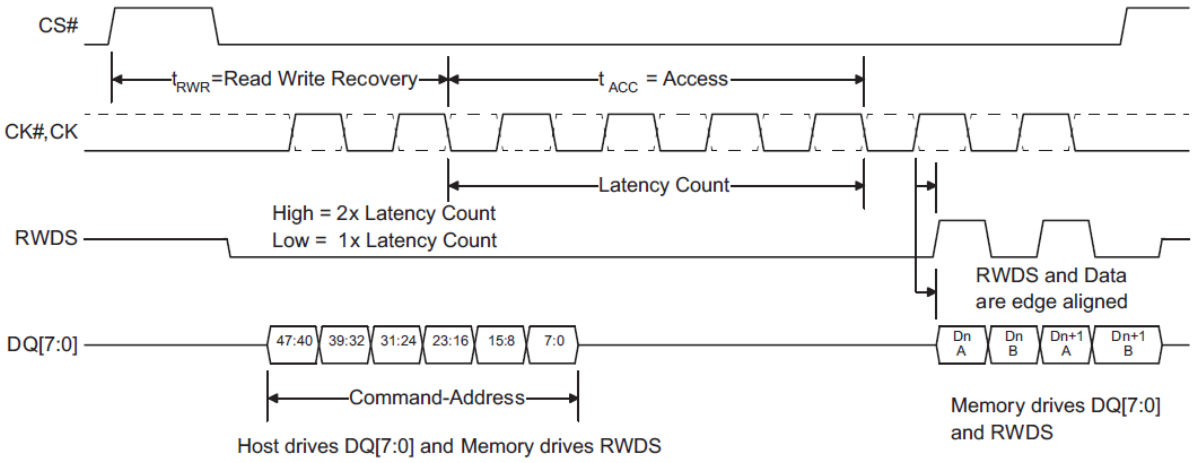

Fig. 35-2 HyperRAM Read Waveform

35.3.1.2 Write

This section describes the write operation of DSMC Core. The DSMC Core asserts CSn,

Rockchip Confidential

CLKP/CLKN, and DQ. Then, it outputs 3 words command/address, and writes 1 or more data. For HyperRAM write operation, there is initial clock latency before writing data.

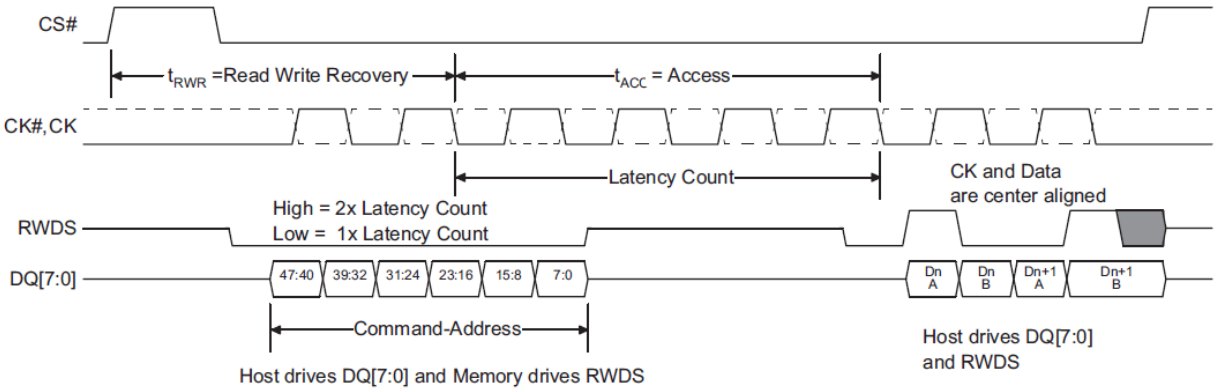

Fig. 35-3 HyperRAM Write Waveform

35.3.1.3 Byte Mask

This DSMC Memory Interface Controller outputs DQS signal as a byte mask during write operation. When byte access is requested from Main Controller, not write data is masked by DQS=HIGH. When target device is HyperFlash, byte masked data is written to device because of only supporting 16-bit access (byte masked data is fill in all 1 bit). In the HyperRAM Write Waveform, the D_n A and D_{n+1} B is invalid data which is masked.

35.3.2 TX/RX Controller

The TX/RX Controller performs operation control by state machine, and flow control of data between AXI bus and DSMC. In addition, when next access address is accepted by multiple outstanding address on AXI bus, it could be merged to the present transaction to improve the bandwidth if the address of subsequent access is continuous address to the present access.

35.3.3 C/A Encoder

DSMC memory device uses 6 bytes of command/address information to define the transactions characteristics. Table below shows the assignments of CA bit in DSMC Memory Interface Controller.

Table 35-1 C/A Format of DSMC for Hyper Device

C/A Bit	Name	Assignment
47	R/W#	0: Write, 1: Read
46	Target	CRT in DSMC_MCRn
45	Burst Type	0: WRAP, 1: INCR
44	RFU	0
43-16	Page Address	Address [31:4]
15	RFU	0
14-13	RFU	3
12-3	RFU	0
2-0	Column Address	Address [3:1]

note: The CA bit function of different devices slightly differs, and the exact meaning nead to be referred to the datasheet of the device.

35.3.4 FIFO

This section describes the FIFO for processing transaction request.

35.3.4.1 ADDR FIFO

ADR FIFO is a synchronizer module from AXI clock domain to DSMC clock domain. This FIFO has 46-bit width. This FIFO stores the control data which includes address, length, burst type and r/w flag. From these data, the control signals are generated for Main Controller.

35.3.4.2 W DAT FIFO

This FIFO is used to store the write data, valid information and strobe information written from the master in order to receive the command sequence of write buffer programming without a wait on AXI interface. The valid information indicates the 8-bit data is valid or not. The strobe information is used for strobe data from AXI interface to DSMC Core. When

Rockchip Confidential

valid and strobe is 1, the 8-bit data is written data.

35.3.4.3 R DAT FIFO

This FIFO is used to store the data read from RX FIFO and the error detection information, and data stored is outputted according to timing of ACLK on AXI interface. This error information is transferred to HOST by RRESP signals.

35.3.5 LocalBus

35.3.5.1 Region division

The internal space of LocalBus device could be divided into different region, and they could be applied in suitable case. The size of regions is configure by DSMC_DEV_SIZE and DSMC_SLV_RGN_DIVn. The attribution of different region could be set to DPRA, REG or FIFO.

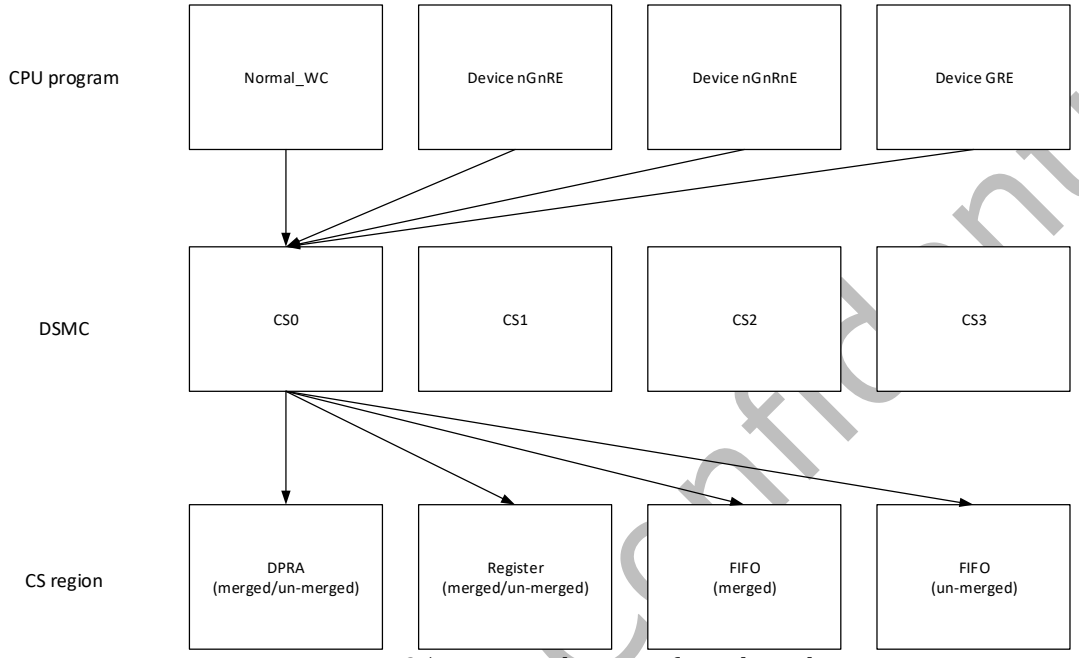

Fig. 35-4 Region division of LocalBus device

35.3.5.2 CA Encoder

Table 35-2 C/A Format of DSMC for LocalBus Device

C/A Bit	Name	Assignment
47	R/W#	0: Read, 1: Write
46	Target	CRT in DSMC_MCRn
45	Burst Type	0: WRAP, 1: INCR
44	Space Type	0: FIFO, 1: DPRA
43	FIFO Merge	0: No Merge, 1: Merge
42	RFU	0
41-40	Region	Region 0/1/2/3
39-32	Length	Burst length
31-0	Address	Address [31:0]

35.3.5.3 Back pressure

The back pressure mechanism is used to make full use of FIFO region space.

In the read transaction, when the FIFO is empty and could not provide data to the DSMC interface, the slave could enter the wait state, in which slave stop to send DQS clock, and latch the output DQ data. When the FIFO is recovered, the slave could continue sending the DQS and DQ, which could save bandwidth comparing to restart another burst.

In the write transaction, when the FIFO is full and could not receive data from the DSMC interface, the asynchronous signal DSMC_RDYN would be asserted. When the DSMC received, it would not send DQ and DSMC_CLK until the DSMC_RDYN is not asserted, which means there are enough space in the slave FIFO to accept data.

Rockchip Confidential

35.4 Register Description

35.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

35.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
DSMC_VER	0x0000	W	0x00000100	IP Version Register
DSMC_CSR	0x0008	W	0x00000000	Controller Status Register
DSMC_TAR	0x0010	W	0x00000000	Transaction Allocation Register
DSMC_AXICTL	0x0014	W	0x00000020	AXI Transaction Control Register
DSMC_CLK_MD	0x0020	W	0x00000000	Clock Mode Register
DSMC_DEV_SIZE	0x0030	W	0x00000017	Device Region Size Register
DSMC_INT_EN	0x0040	W	0x00000000	Interrupt Enable Register

35.6 Application Notes

35.6.1 Typical Program Flow for Hyper Device

1. Configure the DSMC_DEV_SIZE according to the size of device applied.
2. Configure the DSMC_MRGTCRx to support merge operation, and the DSMC_BDRTCRx to support crossing the boundary.
3. Configure the DSMC_MTRx to adjust the transfer timing.
4. Configure DSMC_MCRx to access the slave configure register.
5. Set the slave configuration to be consistent with the host, such as write and read latency.
6. Configure DSMC_MCRx to access the slave memory space.

35.6.2 Typical Program Flow for LocalBus Device

1. Configure the DSMC_DEV_SIZE according to the size of device applied.
2. Configure the DSMC_MRGTCRx to support merge operation, and the DSMC_BDRTCRx to support crossing the boundary.
3. Configure the DSMC_MTRx to adjust the transfer timing.
4. Configure the DSMC_VDMCx to LocalBus.
5. Enable the DSMC_WRAP2INCRx function if the slave required.
6. Configure DSMC_MCRx to access the slave configure register.
7. Keep the configuration parameter of the slave is the same as the master.
8. Configure DSMC_MCRx to access the slave memory space.

35.6.3 Chip Select selection

This section describes how to select Chip Select. This controller can’t assert two Chip Select at the same time except for the LocalBus write.

When the device size is configured, the 2 address bits higher than device size are used as chip select signals.

35.6.4 Configurable CS# Low Time

This section describes configurable CS# low time. HyperRAM has a regulation for CS# low time (t_{CSM}). To meet CS# low time, a read/write transaction can be regulated by setting MCRx.MAXLEN bit. By MCRx.MAXLEN bit, one transaction is split multi transactions.

Rockchip Confidential

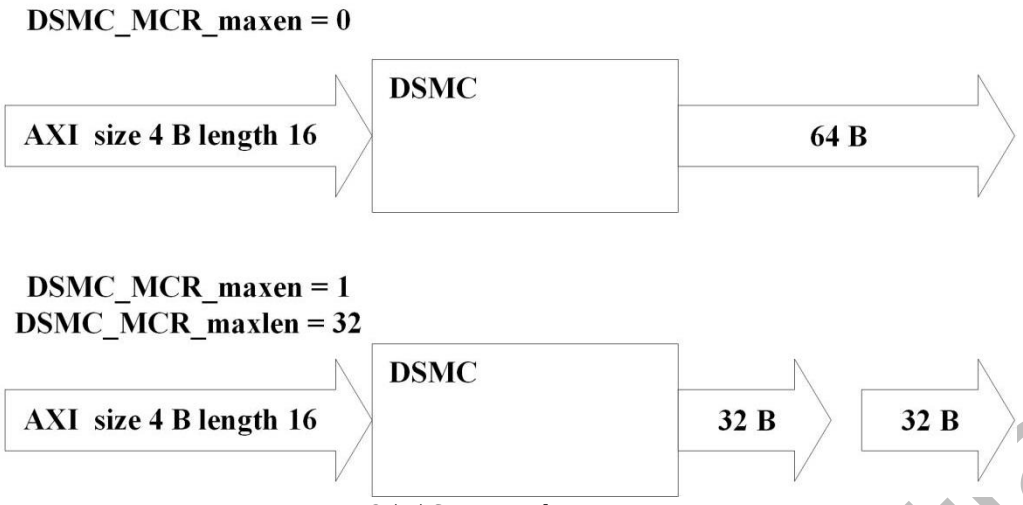

Fig. 35-5 Separated Transaction

35.6.5 Data Map

The data mapping relationship between memory and DSMC interface is shown as below.

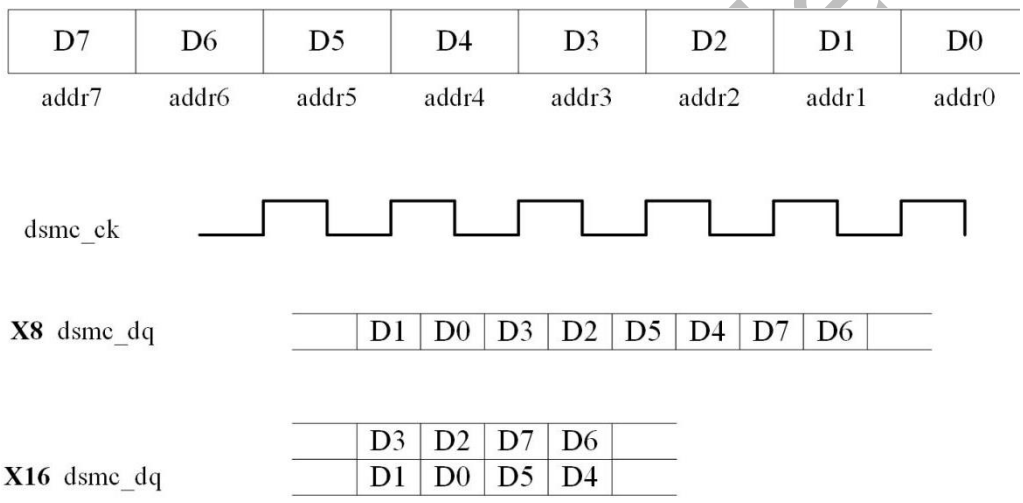

Fig. 35-6 Data mapping relationship between memory and DSMC interface

35.6.6 Merge Operation

The merge operation function supports Hyper device and LocalBus device, and it is configured by the DSMC_MRGTCRx register.

- Merge operation removes address output period and latency cycles for subsequent transaction.
- When DSMC Memory Controller IP accepts subsequent read transaction with continuous address, it is merged to one CS# period on DSMC memory interface.

35.6.7 Timing Adjustment

This section describes the DSMC timing adjustment. DSMC core has timing adjustment circuit and timing adjustment is controlled by DSMC_MTRn. RCSHI, RCSS, and RCSH in DSMC_MTRn are used for the read timing adjustment, and WCSHI, WCSS, and WCSH in DSMC_MTRn are used for the write timing adjustment.

Chapter 36 Slave Double Date Rate Serial Memory Controller (SLAVE DSMC)

36.1 Overview

The Slave DSMC is the slave controller of Rockchip LocalBus, and it works in combination with DSMC. There are two regions of register and FIFO in the SLAVE DSMC to achieve low latency and high bandwidth.

The main feature is shown below

- Support the double data rate interface
- Support 8-wire serial transfer mode
- Support 2 interrupts of host2slave and slave2host
- Support 2 region attributions of register and FIFO
- Support wait state in FIFO read mode
- Support back pressure in FIFO write mode
- Support configurable serial address width: 16 bits or 32 bits in different region
- Support configurable internal bus accessing address

36.2 Block Diagram

SLAVE DSMC is comprised of:

- AHB Interface

The APB Interface implements the AHB slave operation. Its data bus width is 32 bits.

- AXI Interface

The AXI Interface is a XIP interface to access internal device. Its data bus width is 64 bits.

- LocalBus Control Interface

The interface to transmit data with MASTER DSMC.

- Bus Control

The core module to access internal memory in FIFO region.

- Common Register Bank

The DSMC transfer configuration register bank.

- Application & Control Status Register Bank

The SLAVE DSMC control and status register banks, and they are shadow registers.

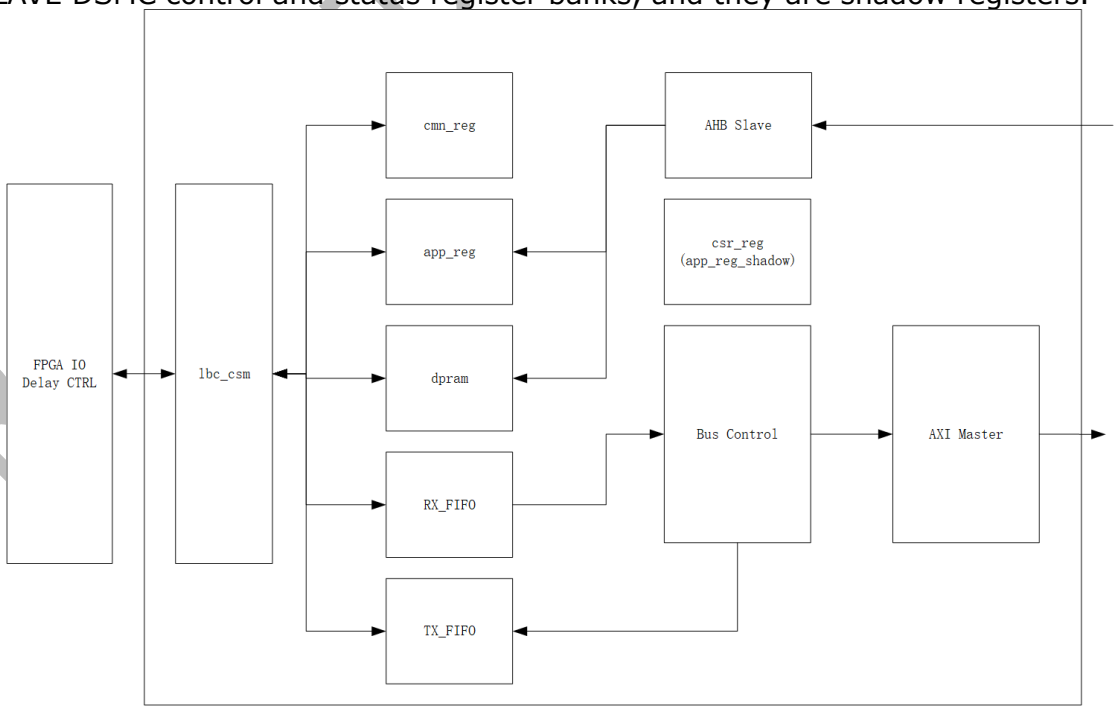

Fig. 36-1 SLAVE DSMC Block Diagram

Rockchip Confidential

36.3 Function Description

The SLAVE DSMC is responsible for transmitting data from the Local Bus to the Register Memory and resolving read/write transmission from the LocalBus to the internal memory space of the slave chip.

The MASTER accesses the CMN_REG and LBC_REG of the LBC_SLAVE through the LocalBus interface, and the slave accesses the APP_REG of the LBC_SLAVE through the AHB interface. The LBC_REG and APP_REG are shadow of each other and can be read but not configured in each other's clock domain.

For data read and write access on the host, the LBC_SLAVE converts the LocalBus transmission to the data transfer of the AXI interface pair on the slave internal memory.

Before the SLAVE DSMC access, the bus must be switch from the flexible bus to the SLAVE DSMC.

36.3.1 DSMC Interface

This section describes physical interface of the SLAVE DSMC module.

36.3.1.1 Read

DSMC asserts cs, dsmc_clk, and dsmc_dq. Then, the SLAVE DSMC receives 3 words command/address, and outputs data by the timing of dqs_clk. The read data is edge aligned with dqs_clk and the read latency is configurable.

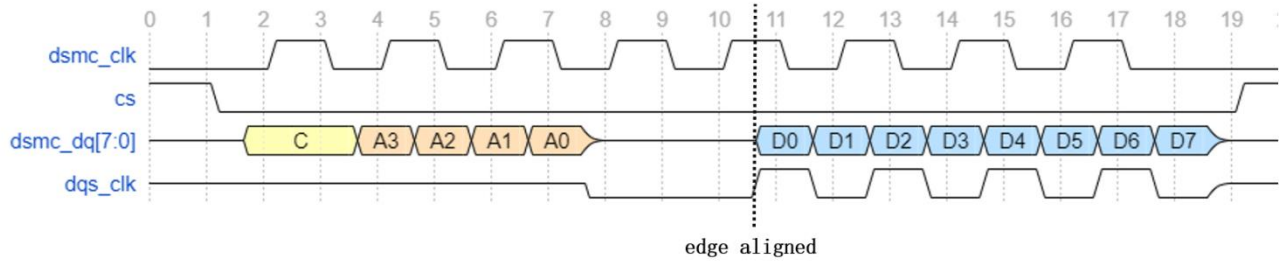

Fig. 36-2 LocalBus Read Waveform

36.3.1.2 Write

This section describes the write operation of LocalBus. The DSMC asserts cs, dsmc_clk, and dsmc_dq. Then, the Slave DSMC receives 3 words command/address, and then the data information. The write data is center aligned with dsmc_clk and the data latency is configurable.

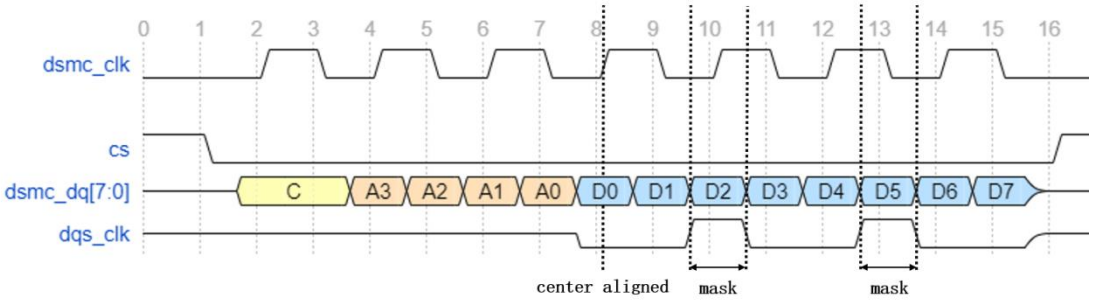

Fig. 36-3 LocalBus Write Waveform

36.3.1.3 Byte Mask

This SLAVE DSMC could also support byte write access as same as the MASTER

36.3.1.4 C/A Encoder

The C/A Encoder could be referred in the corresponding part of the MASTER DSMC.

36.3.2 FIFO Access

The FIFO region could be empty or full due to the bandwidth difference, and the wait state and back pressure is introduced to improve bandwidth.

Rockchip Confidential

36.3.2.1 Read Wait State

In the read transaction, when the FIFO is empty and could not provide data to the DSMC interface, the slave could enter the wait state, in which slave stop to send DQS clock, and latch the output DQ data. When the FIFO is recovered, the slave could continue sending the DQS and DQ, which could save bandwidth comparing to restart another burst.

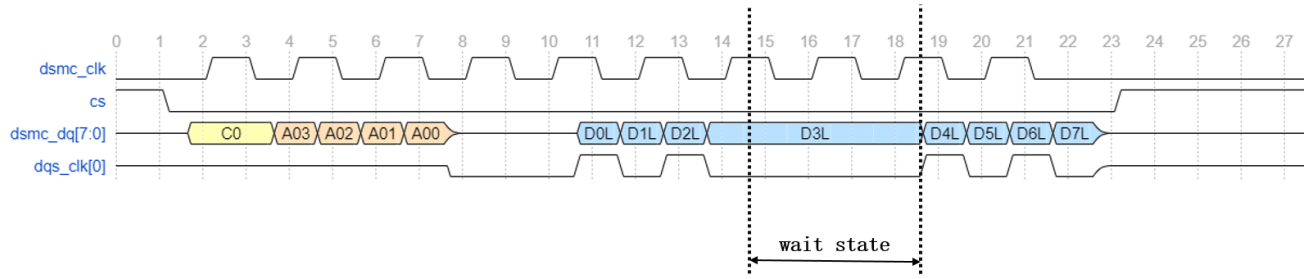

Fig. 36-4 LocalBus Read Waveform

36.3.2.2 Write Back Pressure

In the write transaction, when the FIFO is full and could not receive data from the DSMC interface, the asynchronous signal DSMC_RDYN would be asserted. When the DSMC received, it would not send DQ and DSMC_CLK until the DSMC_RDYN is not asserted, which means there are enough space in the slave FIFO to accept data.

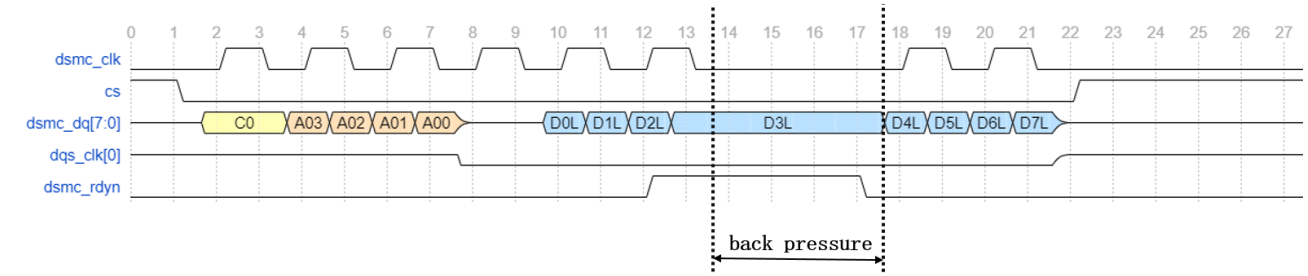

Fig. 36-5 LocalBus Read Waveform

36.4 Register Description

36.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

36.4.3 Detail Registers Description

SLAVE_DSMC_APP_CON0

Address: Operational Base(0xFF880000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con0 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[0]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON1

Address: Operational Base(0xFF880000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con1 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[1]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON2

Address: Operational Base(0xFF880000) + offset (0x0008)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con2 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[2]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON3

Address: Operational Base(0xFF880000) + offset (0x000C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con3 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[3]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON4

Address: Operational Base(0xFF880000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con4 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[4]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON5

Address: Operational Base(0xFF880000) + offset (0x0014)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con5 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[5]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON6

Rockchip Confidential

Address: Operational Base(0xFF880000) + offset (0x0018)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con6 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[6]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON7

Address: Operational Base(0xFF880000) + offset (0x001C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con7 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[7]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON8

Address: Operational Base(0xFF880000) + offset (0x0020)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con8 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[8]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON9

Address: Operational Base(0xFF880000) + offset (0x0024)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con9 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[9]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON10

Address: Operational Base(0xFF880000) + offset (0x0028)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con10 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[10]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON11

Address: Operational Base(0xFF880000) + offset (0x002C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con11 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[11]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON12

Address: Operational Base(0xFF880000) + offset (0x0030)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con12 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[12]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON13

Address: Operational Base(0xFF880000) + offset (0x0034)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con13 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[13]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON14

Address: Operational Base(0xFF880000) + offset (0x0038)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con14 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[14]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_CON15

Address: Operational Base(0xFF880000) + offset (0x003C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	app_con15 Write access will trigger interrupt from slave to host, the interrupt status is lbc_s2h_int_sta[15]. The corresponding shadow register could be read through DSMC interface.

SLAVE_DSMC_APP_H2S_INT_STA

Address: Operational Base(0xFF880000) + offset (0x0080)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	W1C	0x0000	app_h2s_int_sta The interrupt status from host to slave. The interrupt is originating from the writing of LBC_CON.

SLAVE_DSMC_APP_H2S_INT_STA_EN

Address: Operational Base(0xFF880000) + offset (0x0084)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	app_h2s_int_sta_en The interrupt enable registers of 16 h2s interrupt status. 1'b0: disable 1'b1: enable

SLAVE_DSMC_APP_H2S_INT_STA_SIG_EN

Address: Operational Base(0xFF880000) + offset (0x0088)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RW	0x0000	app_h2s_int_sta_sig_en The interrupt signal out registers of 16 h2s interrupt status. 1'b0: disable 1'b1: enable

SLAVE_DSMC_LBC_CON0

Address: Operational Base(0xFF880000) + offset (0x0100)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con0 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[0]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON1

Address: Operational Base(0xFF880000) + offset (0x0104)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con1 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[1]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON2

Address: Operational Base(0xFF880000) + offset (0x0108)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con2 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[2]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON3

Address: Operational Base(0xFF880000) + offset (0x010C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con3 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[3]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON4

Address: Operational Base(0xFF880000) + offset (0x0110)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con4 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[4]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON5

Rockchip Confidential

Address: Operational Base(0xFF880000) + offset (0x0114)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con5 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[5]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON6

Address: Operational Base(0xFF880000) + offset (0x0118)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con6 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[6]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON7

Address: Operational Base(0xFF880000) + offset (0x011C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con7 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[7]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON8

Address: Operational Base(0xFF880000) + offset (0x0120)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con8 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[8]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON9

Address: Operational Base(0xFF880000) + offset (0x0124)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con9 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[9]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON10

Address: Operational Base(0xFF880000) + offset (0x0128)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con10 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[10]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON11

Address: Operational Base(0xFF880000) + offset (0x012C)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con11 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[11]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON12

Address: Operational Base(0xFF880000) + offset (0x0130)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con12 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[12]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON13

Address: Operational Base(0xFF880000) + offset (0x0134)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con13 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[13]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON14

Address: Operational Base(0xFF880000) + offset (0x0138)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con14 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[14]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_CON15

Address: Operational Base(0xFF880000) + offset (0x013C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	lbc_con15 Write access from DSMC will trigger interrupt from host to slave, the interrupt status is app_h2s_int_sta[15]. The corresponding shadow register could be read through Slave AHB interface.

SLAVE_DSMC_LBC_S2H_INT_STA

Address: Operational Base(0xFF880000) + offset (0x0180)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	W1C	0x0000	lbc_s2h_int_sta The interrupt status from slave to host. The interrupt is originating from the writing of APP_CON.

SLAVE_DSMC_LBC_S2H_INT_STA_EN

Address: Operational Base(0xFF880000) + offset (0x0184)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RO	0x0000	lbc_s2h_int_sta_en The interrupt enable registers of 16 s2h interrupt status. 1'b0: disable 1'b1: enable

SLAVE_DSMC_LBC_S2H_INT_STA_SIG_EN

Address: Operational Base(0xFF880000) + offset (0x0188)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	write_enable Write enable for lower 16 bits, each bit is individual. 1'b0: Write access disable 1'b1: Write access enable
15:0	RO	0x0000	lbc_s2h_int_sta_sig_en The interrupt signal out registers of 16 s2h interrupt status. 1'b0: disable 1'b1: enable

SLAVE_DSMC_AXI_WR_ADDR_BASE

Address: Operational Base(0xFF880000) + offset (0x0800)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	axi_wr_addr_base The access base address of write transaction in AXI interface.

SLAVE_DSMC_AXI_RD_ADDR_BASE

Address: Operational Base(0xFF880000) + offset (0x0804)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	axi_rd_addr_base The access base address of read transaction in AXI interface.

SLAVE_DSMC_DBG_STA_0

Address: Operational Base(0xFF880000) + offset (0x0900)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:2	RO	0x0	axi_wr_resp_error AXI write transaction response error.
1:0	RO	0x0	axi_rd_resp_error AXI read transaction response error.

SLAVE_DSMC_DBG_STA_1

Address: Operational Base(0xFF880000) + offset (0x0904)

Bit	Attr	Reset Value	Description
31:4	RO	0x0000000	reserved
3:0	RO	0x0	bus_current_state The state machine of slave.

SLAVE_DSMC_DBG_STA_2

Address: Operational Base(0xFF880000) + offset (0x0908)

Bit	Attr	Reset Value	Description
31:22	RO	0x000	reserved
21:16	RO	0x00	tx_dat_fifo_space2empty The remained FIFO space of TX data FIFO.

Rockchip Confidential

Bit	Attr	Reset Value	Description
15	RO	0x0	reserved
14:8	RO	0x00	rx_dat_fifo_space2empty The remained FIFO space of RX data FIFO.
7:5	RO	0x0	reserved
4:0	RO	0x00	rx_cmd_fifo_space2empty The remained FIFO space of RX command FIFO.

SLAVE_DSMC_VER

Address: Operational Base(0xFF880000) + offset (0x0A00)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000100	version_code The version code of the DSMC slave.

36.5 Common Register Description

36.5.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

36.5.2 Registers Summary

Name	Offset	Size	Reset Value	Description
SLAVE_DSMC_CMN_CMN_CON0	0x0000	W	0x00000211	Common Configuration0
SLAVE_DSMC_CMN_CMN_CON1	0x0004	W	0x00001818	Common Configuration0
SLAVE_DSMC_CMN_CMN_CON2	0x0008	W	0x01010F0F	Common Configuration0
SLAVE_DSMC_CMN_CMN_CON3	0x000C	W	0x00000010	Common Configuration0
SLAVE_DSMC_CMN_RGN0_CMN_CON0	0x0100	W	0x00000221	Region0 Common Configuration0
SLAVE_DSMC_CMN_RGN1_CMN_CON0	0x0200	W	0x00000221	Region1 Common Configuration0
SLAVE_DSMC_CMN_RGN2_CMN_CON0	0x0300	W	0x00000221	Region2 Common Configuration0
SLAVE_DSMC_CMN_RGN3_CMN_CON0	0x0400	W	0x00000221	Region3 Common Configuration0
SLAVE_DSMC_CMN_DBG_STATUS_0	0x0900	W	0x00000000	Debug Status Register0
SLAVE_DSMC_CMN_DBG_STATUS_1	0x0904	W	0x00000000	Debug Status Register1
SLAVE_DSMC_CMN_DBG_STATUS_2	0x0908	W	0x00000000	Debug Status Register2

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

36.5.3 Detail Registers Description

SLAVE_DSMC_CMN_CMN_CON0

Address: Operational Base + offset (0x0000)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11	RW	0x0	wr_data_cyc_extended DSMC will output extended dummy clock cycle in write transaction when accessing CMN register. 1'b0: Normal write cycle mode 1'b1: Extend write cycle mode

Rockchip Confidential

Bit	Attr	Reset Value	Description
10:8	RW	0x2	rd_latency_cyc Read latency cycle when accessing CMN register. 3'h1: 1 clock latency 3'h2: 2 clock latency Others: Reserved
7	RO	0x0	reserved
6:4	RW	0x1	wr_latency_cyc Write latency cycle when accessing CMN register. 3'h1: 1 clock latency 3'h2: 2 clock latency Others: Reserved
3:1	RO	0x0	reserved
0	RW	0x1	ca_cyc This bit is used to indicate the address width of the CA phase when accessing CMN register. 1'b0: 16bit address 1'b1: 32bit address

SLAVE_DSMC_CMN_CMN_CON1

Address: Operational Base + offset (0x0004)

Bit	Attr	Reset Value	Description
31:29	RO	0x0	reserved
28:24	RW	0x00	tx_almost_empty_watermark Data TX FIFO almost full watermark. When the space of TX FIFO is less than this watermark, the almost_empty of RX FIFO will be asserted.
23:21	RO	0x0	reserved
20:16	RW	0x00	tx_almost_full_watermark Data TX FIFO almost full watermark. When the space of TX FIFO is less than this watermark, the almost_full of RX FIFO will be asserted. If the TX FIFO is almost full, slave will stop to send read transaction from AXI interface.
15:14	RO	0x0	reserved
13:8	RW	0x18	rx_almost_empty_watermark Data RX FIFO almost full watermark. When the space of RX FIFO is less than this watermark, the almost_empty of RX FIFO will be asserted.
7:6	RO	0x0	reserved
5:0	RW	0x18	rx_almost_full_watermark Data RX FIFO almost full watermark. When the RX FIFO is almost full, the DSMC master could not continue writing data in slave.

SLAVE_DSMC_CMN_CMN_CON2

Address: Operational Base + offset (0x0008)

Bit	Attr	Reset Value	Description
31:28	RO	0x0	reserved
27:24	RW	0x1	rx_cmd_almost_empty_watermark Data RX command FIFO almost full watermark. When the space of RX command FIFO is less than this watermark, the almost_empty of RX command FIFO will be asserted.
23:20	RO	0x0	reserved
19:16	RW	0x1	rx_cmd_almost_full_watermark Data RX command FIFO almost full watermark. When the space of RX command FIFO is less than this watermark, the almost_full of RX command FIFO will be asserted.

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:12	RO	0x0	reserved
11:8	RW	0xf	axi_burst_rd_len AXI read burst length.
7:4	RO	0x0	reserved
3:0	RW	0xf	axi_burst_wr_len AXI write burst length.

SLAVE_DSMC_CMN_CMN_CON3

Address: Operational Base + offset (0x000C)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4	RW	0x1	rdyn_gen_ctrl The capacity of RX FIFO will be made full use in enhanced mode. 1'b0: normal 1'b1: enhance
3:1	RO	0x0	reserved
0	RW	0x0	data_width The data width configuration of slave. 1'b0: X8 1'b1: X16

SLAVE_DSMC_CMN_RGN0_CMN_CON0

Address: Operational Base + offset (0x0100)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11	RW	0x0	wr_data_cyc_extended DSMC will output extended dummy clock cycle in write transaction when accessing region0. 1'b0: Normal write cycle mode 1'b1: Extend write cycle mode
10:8	RW	0x2	rd_latency_cyc Read latency cycle when accessing region0. 3'h1: 1 clock latency 3'h2: 2 clock latency Others: Reserved
7	RO	0x0	reserved
6:4	RW	0x2	wr_latency_cyc Write latency cycle when accessing region0. 3'h1: 1 clock latency 3'h2: 2 clock latency Others: Reserved
3:1	RO	0x0	reserved
0	RW	0x1	ca_cyc This bit is used to indicate the address width of the CA phase when accessing region0. 1'b0: 16bit address 1'b1: 32bit address

36.7 Application Notes

36.7.1 Typical Program Flow

7. Configure the SLAVE_DSMC_AXI_WR_ADDR_SIZE and SLAVE_DSMC_AXI_RD_ADDR_SIZE according to Chip Address Map.
8. The MASTER DSMC configures the Common register bank according to the host setting.
9. The MASTER access the register of FIFO region.

36.7.2 Bulk Data Transfer Program Flow

9. Configure the SLAVE_DSMC_AXI_WR_ADDR_SIZE and SLAVE_DSMC_AXI_RD_ADDR_SIZE according to Chip Address Map.
10. Configure the SLAVE_DSMC_LBC_H2S_INT_STA_EN and SLAVE_DSMC_LBC_H2S_INT_STA_SIG_EN to allow the host to interrupt to slave.
11. The MASTER DSMC configures the Common register bank according to the host setting.
12. The slave chip sends DMA request interrupt signal to the host chip, and the host chip start DMA transfer.
13. The host chip access application register bank to generate host2slave interrupt to inform the slave chip that the transfer is finished.

Chapter 37 Flexible Bus (FlexBUS)

37.1 Overview

FlexBUS is an AHB slave device. FlexBUS can achieve high-speed IO toggle and imitate some irregular or standards protocols. There are four possible combinations for the serial clock phase and polarity. The chip select signal (csn) is held high when the FlexBUS is idle or disabled. There are two channels which are transmission channel and receiving channel in FlexBUS. Therefore, FlexBUS can support both transmitting and receiving simultaneously. The flexbus0_clk, flexbus0_csn and flexbus0_data ports can be used for transmission channel and receiving channel. The flexbus1_clk, flexbus1_csn and flexbus1_data ports can only be used for receiving channel.

FlexBUS Controller supports the following features:

- Support for built-in DMA and ping-pong operation for allocating two address
- Support for filling in all 0 if the last DMA burst is less than 32Bytes or 64Bytes in receiving mode
- Support timeout interrupt of DMA response
- The direction of flexbus0_data port is I/O, flexbus0_data port can be used for transmission and receiving operation. The direction of flexbus1_data port is Input, flexbus1_data port can only be used for receiving operation
- Support for four working modes
  - Flexbus0_data port is used for transmission channel and receiving channel, flexbus0_clk port is used for transmission channel and receiving channel, supporting three mode: transmit only, receive only, transmission then receive
  - Flexbus0_data port is only used for transmission channel, flexbus0_clk port is used for transmission channel and receiving channel, supporting four mode: transmit only, receive only, transmission then receive, transmission and receive
  - Flexbus0_data port is only used for transmission channel, flexbus0_clk port is only used for transmission channel, supporting three mode: transmit only, receive only, transmission and receive
- Support software configuration and following data for csn port
- Support the image format of BT601 YUV422 and RGB565
- Support YUV422 image format conversion of RGB888
- Support image cropping function
- Support clock port two modes, free running and following data mode
  - Free running mode
    - Txfifo is empty and supports the following two processing modes
      1) Stop transmission, pull up csn and send abnormal interruption
      2) Data, csn remain unchanged and clock hold toggle, send abnormal interruption
    - Rxfifo is pre-full
      1) Stop transmission, pull up csn and send abnormal interruption
  - Following data mode
    - Txfifo is empty and supports the following two processing modes
      1) Stop transmission, pull up csn and send abnormal interruption
      2) Data, csn and clock remain unchanged, send abnormal interruption
    - Rxfifo is pre-full and supports the following two processing modes
      1) Stop transmission, pull up csn and send abnormal interruption
      2) Data, csn and clock remain unchanged, send abnormal interruption
- Support single mode and continuous mode. Continuous mode can not support transmission then receive mode
- Support configurable four possible combinations for the clock port polarity and phase
- Support 1,2,4,8,16bits parallel data transfer
- Support clock port masking function
- Support the maximum of clock port up to 100MHz in transmission mode and receive mode
- Support software configuration modification of sampling points

Rockchip Confidential

37.2 Block Diagram

The FlexBUS Controller comprises with:

- **AHB_CFG**

The AHB_CFG contains control registers of transmitters and receiver.

- **AXI Master Interface and DMA Controller**

The AXI Master Interface and DMA Controller implement for reading data from DDR and writing data to DDR.

- **Engine**

The Engine implements control over all modules and monitor the generation of abnormal interrupts.

- **IOBUF**

The IOBUF implements logic of data, csn and clock port.

- **TX and RX FIFO**

The TX FIFO is the buffer to store transmitted data. The TX FIFO is the buffer to store received data. The size of the TX and RX FIFO is 32bits x 256.

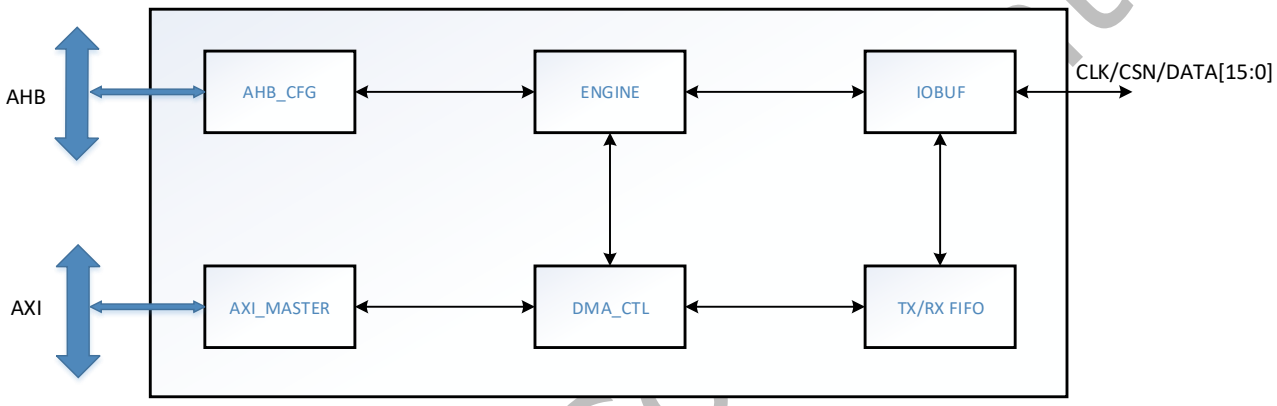

Fig. 37-1 FlexBUS Controller Block diagram

37.3 Function Description

37.3.1 Transfer Modes

According to multiplexed of flexbus0_data and flexbus0_clk ports, FlexBUS can be divided into different working modes. The following table shows the ports in different transfer modes.

Table 37-1 FlexBUS Tranfer Modes Port List

COM_CTL[3:2]	TX Only	RX Only	TX and RX	TX then RX
2'b11	flexbus0_data/ flexbus0_clk/ flexbus0_csn/	flexbus0_data/ flexbus0_clk/ flexbus0_csn/	not support	flexbus0_data/ flexbus0_clk flexbus0_csn
2'b01		flexbus1_data/ flexbus0_clk/ flexbus0_csn	flexbus0_data/flexbus1_data flexbus0_clk/ flexbus0_csn/	flexbus0_data/flexbus1_data flexbus0_clk flexbus0_csn
2'b00		flexbus1_data/ flexbus1_clk/ flexbus1_csn/	flexbus0_data/flexbus1_data flexbus0_clk/flexbus1_clk flexbus0_csn/flexbus1_csn	not support

37.3.2 Free Running

Flexbus0/1_clk can output earlier than csn begin active in free running mode. Flexbus0/1_clk can output as soon as FLEXBUS_FREE_SCLK is configured to 1. When FLEXBUS_FREE_SCLK is configured to 0, Flexbus0/1_clk will follow data after flexbus0/1_csn being active.

37.3.3 Single and Continuous Mode

37.3.3.1 Single Mode

In this mode, the amount of data transmitted or received is determined by FLEXBUS_TX_NUM/RX_NUM. FlexBUS will stop and send interrupt when the amount of data transmitted or received reaches the FLEXBUS_TX_NUM/RX_NUM. The address of

Rockchip Confidential

transmission is FLEXBUS_DMA_SRC_ADDR0/DMA_DST_ADDR0. If the value of FLEXBUS_TX_NUM/RX_NUM is greater than FLEXBUS_DMA_SRC_LEN0/DMA_DST_LEN0, FlexBUS will automatically jump to FLEXBUS_DMA_SRC_ADDR1/DMA_DST_ADDR1 after FLEXBUS_DMA_SRC_ADDR0/ DMA_DST_ADDR0 is full. So it is recommended that the value of FLEXBUS_TX_NUM/RX_NUM is smaller than FLEXBUS_DMA_SRC_LEN0/DMA_DST_LEN0 in single mode.

37.3.3.2 Continuous Mode

In continuous mode, FlexBUS keeps working until the value of FLEXBUS_STOP is set and FLEXBUS_RX_NUM/TX_NUM will be ignored. FlexBUS will send interrupt when FLEXBUS_STOP is set. The user can configures two buffer which buffer0 is configured by FLEXBUS_DMA_SRC_ADDR0/DMA_DST_ADDR0 and FLEXBUS_DMA_SRC_LEN0/DMA_DST_LEN0, buffer1 is configured by FLEXBUS_DMA_SRC_ADDR1/DMA_DST_ADDR1 and FLEXBUS_DMA_SRC_LEN1/DMA_DST_LEN1. After the amount of data transmitted and received reaches the value of buffer0, FlexBUS will automatically jump to buffer1 and the user can configure new address of buffer0 and clear buffer0 interrupt status. Similarly, FlexBUS will automatically jump to buffer0 and the user can configure new address of buffer1 and clear buffer1 interrupt status after the amount of data transmitted and received reaches the value of buffer1.

37.3.4 CPOL and CPHA

The clock polarity (CPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. This is same as SPI. To transmit data, both FlexBUS and peripherals must have identical serial clock phase (CPHA) and clock polarity (CPOL) values. The data frame can be 1/2/4/8/16 bits in length.

When the configuration parameter CPHA = 0, data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the data lines prior to the first serial clock edge. The following two figures show a timing diagram for FlexBUS data transfer with CPHA = 0. The serial clock is shown for configuration parameters CPOL = 0 and CPOL = 1.

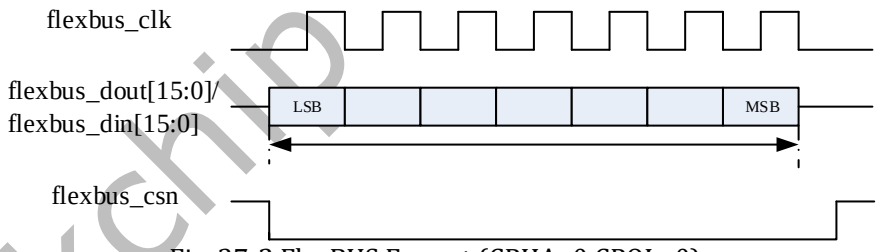

Fig. 37-2 FlexBUS Format (CPHA=0 CPOL=0)

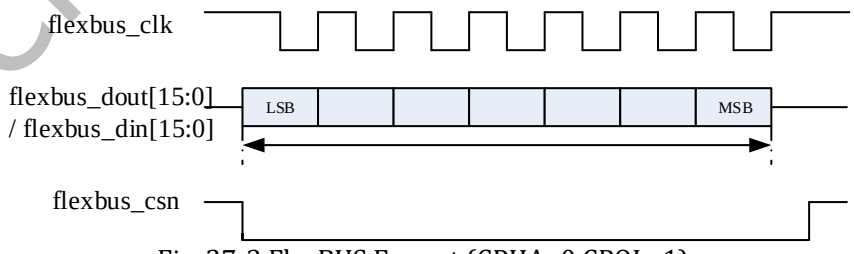

Fig. 37-3 FlexBUS Format (CPHA=0 CPOL=1)

When the configuration parameter CPHA = 1, both master and slave peripherals begin transmitting data on the first serial clock edge after the slave select line is activated. The first data bit is captured on the second (trailing) serial clock edge. Data are propagated by the master and slave peripherals on the leading edge of the serial clock. During continuous data frame transfers, the slave select signal may be held active-low until the last bit of the last frame has been captured. The following two figures show the timing diagram for the FlexBUS format when the configuration parameter CPHA = 1.

Rockchip Confidential

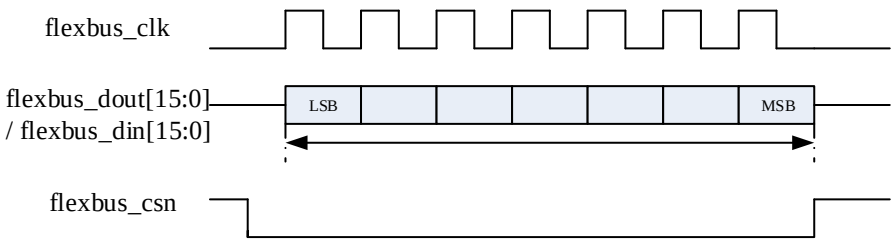

Fig. 37-4 FlexBUS Format (CPHA=1 CPOL=0)

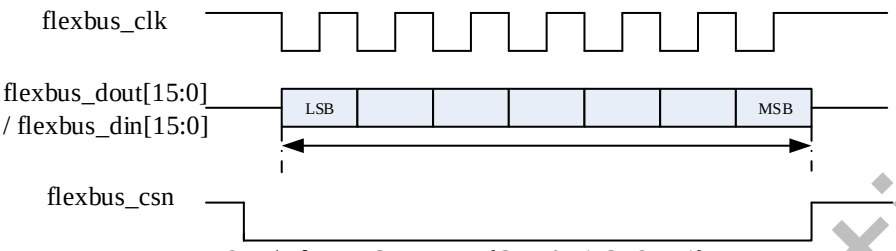

Fig. 37-5 FlexBUS Format (CPHA=1 CPOL=1)

37.3.5 TX Then RX Mode

CPHA=1, CPOL=0, transmit data at the posedge of CLKA and receive data at the negedge of CLKA. At T2, the last data is transmitted, and at T3, data pad would change to input. When FLEXBUS_RXCLK_DUMMY[4:0]=0, at T3 negedge of CLKA, rx channel would sample data; when FLEXBUS_RXCLK_DUMMY[4:0]=1, at T4 negedge of CLKA, rx channel would sample data.

RGB565 For B first

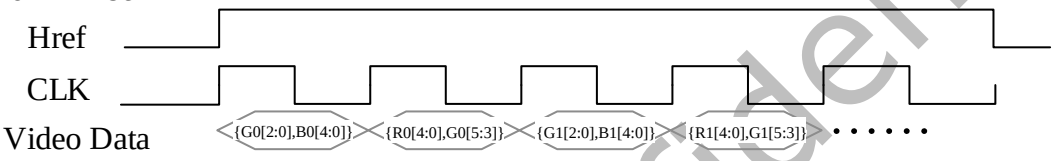

Fig. 37-13 Timing Diagram When B Data First

RGB565 For R first

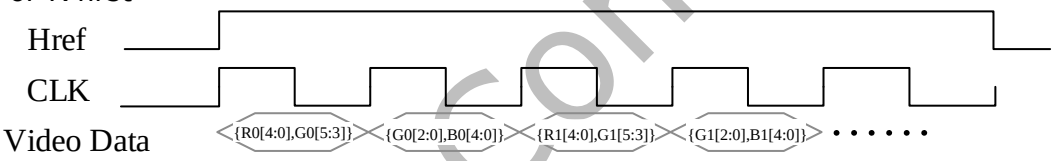

Fig. 37-14 Timing Diagram When R Data First

37.3.6.4 One Frame Stop Mode

In this mode, configure the register FLEXBUS_RX_CTL to one frame stop mode. After one frame captured, FlexBUS will automatic stop and send interrupt. FlexBUS will not capture the sensor data. The address of Y/UV is FLEXBUS_DMA_DST_ADDR0.

37.3.6.5 Frame Ping-Pong Mode

After one frame(F0) captured, FlexBUS will jump to buffer1 and start to capture the next frame(F1) automatically, and host must assign new address pointer of frame0 and clear the frame0 status, thus FlexBUS will capture the third frame automatically(by new F0 address) without any stop and so on for the following frames.

37.3.6.6 Storage

Y/UV data or R/G/B data will be storage in the same buffer. In addition, the amount of data in a row must be an integer multiple of 4Bytes.

37.3.6.7 Crop

The register FLEXBUS_DVP_CROP_START defines the coordinate of crop start point. And the frame size after cropping is following the value of FLEXBUS_DVP_CROP_SIZE. Bypass or crop the source video data to a smaller size destination.

Rockchip Confidential

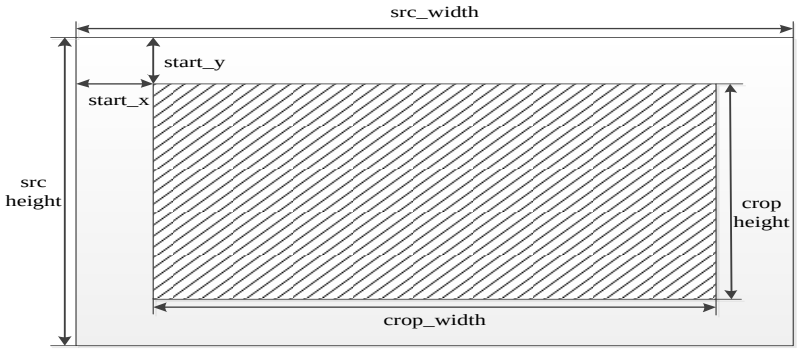

Fig. 37-15 Crop

37.3.7 QSPI

37.3.7.1 Command and Address

There are three phases in QSPI mode, which are command phase, address phase and data phase. The user can configure FLEXBUS_TX_CMD0 and FLEXBUS_TX_CMD1 in command and address phase. The register FLEXBUS_TX_CMD0 and FLEXBUS_TX_CMD1 can store up to 64bits data and data is sent from MSB of TX_CMD0 and TX_CMD1. FlexBUS can support x1 and x4 for command phase and address phase.

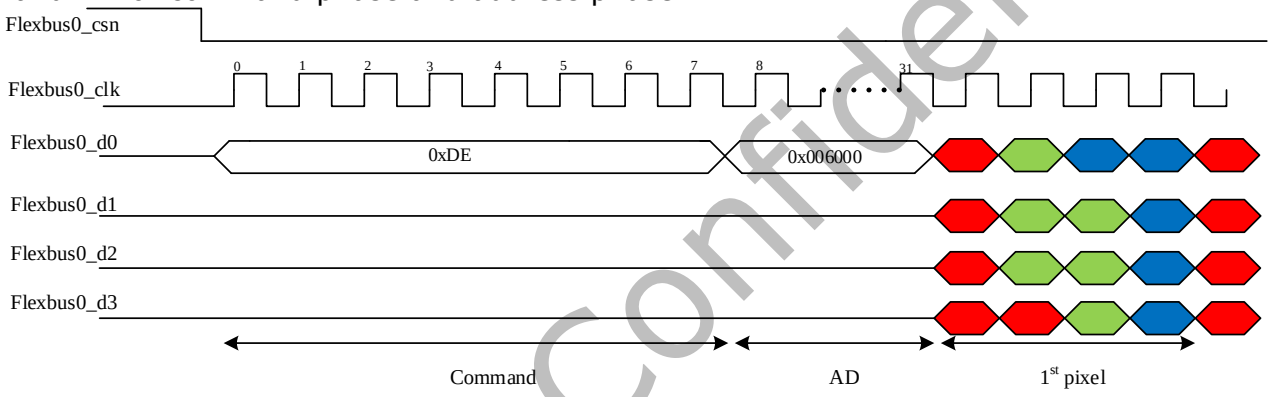

Fig. 37-16 Timing diagram in QSPI Mode

The user can configure FLEXBUS_TX_CMD0 = 0xDE006000 to achieve the timing shown in the figure above.

37.3.7.2 Multi-Line

FlexBUS can support multi-line transfer mode. The command and address should be same on each line of transmission. FLEXBUS_TX_CMD_LEN controls the length of the command and address, which unit is determined by FLEXBUS_TX_CTL[12](1bit or 4bits).
FLEXBUS_TX_WIDTH controls the length of pixel data per line, which unit is determined by FLEXBUS_TX_CTL[31:29]. Flexbus0_csn will automatically be switched to high level when a line of pixel data is sent. The duration of high level is determined by FLEXBUS_TX_CSN_DUMMY.
The relation between FLEXBUS_TX_NUM and FLEXBUS_TX_WIDTH/FLEXBUS_TX_CMD_LEN is as follows:
FLEXBUS_TX_NUM = (number of lines) x (FLEXBUS_TX_WIDTH + FLEXBUS_TX_CMD_LEN).

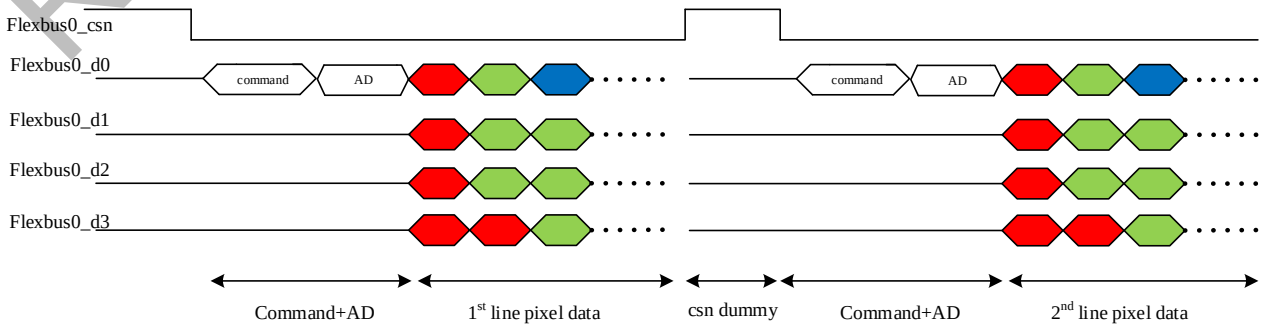

Fig. 37-17 Timing diagram in Multi-line

FLEXBUS_STOP

Address: Operational Base(0xFF880000) + offset (0x0014)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	R/WSC	0x0	rx_stop In rx continue mode, used to stop receive.
0	R/WSC	0x0	tx_stop If set to 1, it used to stop transmit in continue mode.

FLEXBUS_SLAVE_MODE

Address: Operational Base(0xFF880000) + offset (0x0018)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	RW	0x0	dvp_sel 1'b0: Work as ADC 1'b1: Work as DVP interface
0	RW	0x1	clk1_in If set to 1, slave mode is enabled and rx logic uses flexbus_clk1_in as the 2xclk.

FLEXBUS_DVP_POL

Address: Operational Base(0xFF880000) + offset (0x001C)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1	RW	0x0	href_pol 1'b1: High active. 1'b0: Low active.
0	RW	0x0	vsync_pol 1'b1: High active. 1'b0: Low active.

FLEXBUS_DVP_CROP_SIZE

Address: Operational Base(0xFF880000) + offset (0x0020)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	sw_height The expected height of received image.
15:0	RW	0x0000	sw_width The expected width of received image. The value of the register is equal to the number of bytes. So if one pixel is equal to 2bytes, the value of the register is double to width of image.

FLEXBUS_DVP_CROP_START

Address: Operational Base(0xFF880000) + offset (0x0024)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	sw_start_y The vertical ordinate of the start point.
15:0	RW	0x0000	sw_start_x The horizontal ordinate of the start point. The value of the register is equal to the number of bytes. So if one pixel is equal to 2bytes, the value of the register is double to width of image.

FLEXBUS_DVP_ORDER

Address: Operational Base(0xFF880000) + offset (0x0028)

Bit	Attr	Reset Value	Description

FLEXBUS_TX_CTL

Address: Operational Base(0xFF880000) + offset (0x0040)

Bit	Attr	Reset Value	Description
31:29	RW	0x0	data_width Selects the data frame length. 3'b000: 1bit data 3'b001: 2bit data 3'b010: 4bit data 3'b011: 8bit data 3'b100: 16bit data
28:17	RO	0x000	reserved
16	RW	0x0	oen_pre To improve the data IO timing of switching from input to output, the application can set this register to switch IO from input to output in advance for one cycle. Unit is 2xclk. 1'b0: Zero 1'b1: One cycle

Rockchip Confidential

Bit	Attr	Reset Value	Description
15	RW	0x0	oen_dly To improve the data IO timing of switching from output to input, the application can set this register to extend data IO output time at the last 1xclk. Unit is 2xclk. 1'b0: One cycle 1'b1: Two cycle
14	RW	0x0	dat_unit 1'b0: Unit is word when shift is 1'b1. 1'b1: Unit is byte when shift is 1'b1.
13	RW	0x0	shift 1'b0: First parallel bit is LSB in shift register. 1'b1: First parallel bit is MSB in shift register.
12	RW	0x0	cmd_width Command and address line width. 1'b0: x1 mode. 1'b1: x4 mode.
11	RW	0x0	multi_line 1'b1: Multi-line transmission and csn auto switching is enable. 1'b0: Multi-line transmission and csn auto switching is disable.
10:9	RW	0x0	csn_pos_cnt_cfg The register should be configured to define the number of the 2xclk cycles between csn inactive and data stop transmission. Unit is 2xclk. 2'b00: 2 cycles delay 2'b01: 3 cycles delay 2'b10: 4 cycles delay 2'b11: 5 cycles delay
8:7	RW	0x0	csn_neg_cnt_cfg The register should be configured to define the number of the 1xclk cycles between csn active and data active. Unit is 1xclk. 2'b00: Do not delay 2'b01: half cycle delay 2'b10: one cycles delay 2'b11: one and half cycles delay
6	RW	0x0	cutoff_cfg Cutoff function enable/disable. When txfifo is empty, tx logic will stop 1xclk until txfifo is not empty. 1'b1: Enable 1'b0: Disable
5	RW	0x0	1xclk_mask 1xclk mask enable/disable. 1'b1: Enable 1'b0: Disable
4	RW	0x0	continue_mode Continue mode enable/disable. 1'b1: Enable 1'b0: Disable
3	RW	0x0	cpol 1'b0: Inactive state of 1xclk is low. 1'b1: Inactive state of 1xclk is high.
2	RW	0x0	cpha 1'b0: 1xclk toggles in middle of first data bit. 1'b1: 1xclk toggles at start of first data bit.
1:0	RO	0x0	reserved

FLEXBUS_TX_NUM

Rockchip Confidential

Address: Operational Base(0xFF880000) + offset (0x0044)

Bit	Attr	Reset Value	Description
31:27	RO	0x00	reserved
26:0	RW	0x0000000	num The register field sets the number of data frames to transmit. The FlexBUS continues to transmit data until the number of data frames transmitted is equal to this register value. Unit is data_width.

FLEXBUS_TXWAT_START

Address: Operational Base(0xFF880000) + offset (0x0048)

Bit	Attr	Reset Value	Description
31:9	RO	0x000000	reserved
8:0	RW	0x000	txfifo_wat_start When the number of words in transmit FIFO is more than or equal to this value, the transmit logic starts work. Unit is word.

FLEXBUS_TXFIFO_DNUM

Address: Operational Base(0xFF880000) + offset (0x004C)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RO	0x000	dnum Contains the number of valid data entries in the transmit FIFO. Unit is word.

FLEXBUS_TX_WIDTH

Address: Operational Base(0xFF880000) + offset (0x0050)

Bit	Attr	Reset Value	Description
31:12	RO	0x00000	reserved
11:0	RW	0x000	width_size In tx multi-line mode, the number of data will be transmitted when csn is low at one time, excluding command length. Unit is data_width.

FLEXBUS_TX_CSN_DUMMY

Address: Operational Base(0xFF880000) + offset (0x0054)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0000	csn_dummy The register should be configured to define the number of the 2xclk cycles between csn inactive and csn active. Unit is 2xclk.

FLEXBUS_TX_CMD_LEN

Address: Operational Base(0xFF880000) + offset (0x0058)

Bit	Attr	Reset Value	Description
31:7	RO	0x0000000	reserved
6:0	RW	0x00	cmd_len The number of data will be transmitted in one wire mode. Unit is bit. The minimum configured value should be greater than 1.

FLEXBUS_TX_CMD0

Address: Operational Base(0xFF880000) + offset (0x005C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	cmd0 Data used to transmit in one wire mode.

Rockchip Confidential

FLEXBUS_TX_CMD1

Address: Operational Base(0xFF880000) + offset (0x0060)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	cmd1 Data used to transmit in one wire mode.

FLEXBUS_RX_CTL

Address: Operational Base(0xFF880000) + offset (0x0080)

Bit	Attr	Reset Value	Description
31:29	RW	0x0	data_width Selects the data frame length. 3'b000: 1bit data 3'b001: 2bit data 3'b010: 4bit data 3'b011: 8bit data 3'b100: 16bit data
28:18	RO	0x000	reserved
17	RW	0x0	fill_dummy FlexBUS will automatically fill in dummy 0 when the last data is not enough to make up for 4bytes. 1'b1: Enable 1'b0: Disable
16	RW	0x0	dat_unit 1'b0: Unit is word when shift is 1'b1. 1'b1: Unit is byte when shift is 1'b1.
15	RW	0x0	shift 1'b0: First parallel bit is LSB in shift register. 1'b1: First parallel bit is MSB in shift register.
14	RW	0x0	auto_pad When the remaining number of data entries in rxfifo is less than one burst data of DMA, the DMA request will not be set high, but if this bit set to 1, the DMA request will be raised, and 0 will be automatically added to make up for the data volume.
13:9	RW	0x00	csn_pos_cnt_cfg The register should be configured to define the number of the 2xclk cycles between csn inactive and data stop receiving. Unit is 2xclk. 5'b00: 1 cycle delay 5'b01: 2 cycles delay 5'b10: 3 cycles delay 5'b11: 4 cycles delay 5'h1f: Max 32 cycles delay
8:7	RW	0x0	csn_neg_cnt_cfg The register should be configured to define the number of the 1xclk cycles between csn active and data active. 2'b00: Do not delay 2'b01: half cycle delay 2'b10: one cycles delay 2'b11: one and half cycles delay
6	RW	0x0	cutoff_cfg Cutoff function enable/disable. When rxfifo is full, rx logic will stop 1xclk until rxfifo is not full. 1'b1: Enable 1'b0: Disable

Rockchip Confidential

Bit	Attr	Reset Value	Description
5	RW	0x0	rxd_dy If the rxd data cannot be sampled by the sclk edge at the right time, this register should be configured to define the number of the 2xclk cycles after the active 1xclk edge to sample rxd data later when FlexBUS works at high frequency. Unit is 2xclk. 1'b0: Do not delay 1'b1: One cycle delay
4	RW	0x0	continue_mode Continue mode enable/disable. 1'b1: Enable 1'b0: Disable
3	RW	0x0	cpol 1'b0: Inactive state of 1xclk is low. 1'b1: Inactive state of 1xclk is high.
2	RW	0x0	cpha 1'b0: 1xclk toggles in middle of first data bit. 1'b1: 1xclkl clock toggles at start of first data bit.
1:0	RO	0x0	reserved

FLEXBUS_RX_NUM

Address: Operational Base(0xFF880000) + offset (0x0084)

Bit	Attr	Reset Value	Description
31:27	RO	0x00	reserved
26:0	RW	0x0000000	num The register field sets the number of data frames to receive. The FlexBUS continues to receive data until the number of data frames transmitted is equal to this register value. This value contains rx_clk_dummy. Unit is data_width.

FLEXBUS_RXFIFO_DNUM

Address: Operational Base(0xFF880000) + offset (0x0088)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved
9:0	RO	0x000	dnum Contains the number of valid data entries in the receive FIFO. Unit is word.

FLEXBUS_DLL_EN

Address: Operational Base(0xFF880000) + offset (0x008C)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	enable If set to 1, rx delayline clock is enable.

FLEXBUS_DLL_NUM

Address: Operational Base(0xFF880000) + offset (0x0090)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x00	num The number steps of delayline.

FLEXBUS_RXCLK_DUMMY

Address: Operational Base(0xFF880000) + offset (0x0094)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
4:0	RW	0x00	rx_clk_dummy In transmission then receive mode, this register should be configured to define the number of the 1xclk cycles after transmit operation finish to sample rx data. Unit is 1xclk.

FLEXBUS_RXCLK_CAP_CNT

Address: Operational Base(0xFF880000) + offset (0x0098)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4:0	RW	0x00	rx_cap_cnt Used to define the position of the first data being captured. Unit is 1xclk.

FLEXBUS_DMA_RD_OUTSTD

Address: Operational Base(0xFF880000) + offset (0x0100)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RW	0x0f	read_outstanding DMA read outstanding is equal to (register + 1).

FLEXBUS_DMA_WR_OUTSTD

Address: Operational Base(0xFF880000) + offset (0x0104)

Bit	Attr	Reset Value	Description
31:6	RO	0x0000000	reserved
5:0	RW	0x0f	write_outstanding DMA write outstanding is equal to (register + 1).

FLEXBUS_DMA_SRC_ADDR0

37.6 Application Notes

Clock Ratios

The frequency of PAD is half of FlexBUS operation clock. When FlexBUS operation clock is 200MHz, the frequency of flexbus0_clk and flexbus1_clk is 100MHz.

FSPI Transfer Flow

If want to support FSPI feature, the configuration is showing as below:

A. Set GRF_SOC_CON1[1]=1 to as master; set modes, transmit then receive, FLEXBUS_COM_CTL[3:0]=4'hf;
B. Set RX CLK dummy counter, FLEXBUS_RXCLK_DUMMY;
C. Set Interrupt mask, FLEXBUS_IMR;
D. Set format of transmit data, FLEXBUS_TX_CTL;
E. Set tx start water line, FLEXBUS_TXWAT_START;
F. Set tx length, FLEXBUS_TX_NUM;
G. Set format of receive data, FLEXBUS_RX_CTL;
H. Set rx length, FLEXBUS_RX_NUM;
I. Set DMA,FLEXBUS_DMA_SRC_ADDR0/DST_ADDR0/SRC_LEN0/DST_LEN0;
J. Set FlexBUS enable, FLEXBUS_ENR[1:0]=2'b11;

Wait Interrupt and clear interrupt;
Final, disable FlexBUS.

ADC with Sync CLKIN Transfer Flow

A. Set GRF_SOC_CON1[1] based on ADC interface timing and set GRF_SOC_CON1[1]=0 to

Rockchip Confidential

as slave;
B. Set modes, rx only mode, FLEXBUS_COM_CTL[3:0]=4'h2;
C. Set Interrupt mask, FLEXBUS_IMR;
D. Set format of receive data, FLEXBUS_RX_CTL[4]=1, data frame configuration according to actual usage;
E. Set FLEXBUS_SLAVE_MODE=2'b01;
F. Set DMA;
G. Set FlexBUS enable, FLEXBUS_ENR[1]=1'b1;
H. Wait interrupt, if dma_dst0 is active indicating that buffer0 has finished and clear interrupt, FlexBUS can set new buffer0 address. FlexBUS will automatically jump to buffer1 address and capture new data; If don't want to receive data, set FLEXBUS_STOP[1]=1, and then disable FlexBUS;
I. Wait interrupt, if dma_dst1 is active indicating that buffer1 has finished and clear interrupt, FlexBUS can set new buffer1 address. FlexBUS will automatically jump to buffer0 address and capture new data; If don't want to receive new data, Set FLEXBUS_STOP[1]=1, and then disable FlexBUS;
J. If want to stop receiving data , set FlexBUS.STOP[1]=1 at any time and wait rx_done interrupt; final disable FlexBUS;
K. If want to continue to receive data, repeat H-I.

ADC without CLKIN Transfer Flow
A. Set GRF_SOC_CON1[1]=1;
B. Set modes, rx only mode, FLEXBUS_COM_CTL[3:0]=4'h2;
C. Set Interrupt mask, FLEXBUS_IMR;
D. Set format of receive data, FLEXBUS_RX_CTL[4]=1, data frame configuration according to actual usage;
E. Set DMA;
F. Set FlexBUS enable, FLEXBUS_ENR[1]=1'b1;
G. Wait interrupt, if dma_dst0 is active indicating that buffer0 has finished and clear interrupt, FlexBUS can set new buffer0 address. FlexBUS will automatically jump to buffer1 address and capture new data; If don't want to receive data, set FLEXBUS_STOP[1]=1, and then disable FlexBUS;
H. Wait interrupt, if dma_dst1 is active indicating that buffer1 has finished and clear interrupt, FlexBUS can set new buffer1 address. FlexBUS will automatically jump to buffer0 address and capture new data; If don't want to receive new data, Set FLEXBUS_STOP[1]=1, and then disable FlexBUS;
I. If want to stop receiving data , set FlexBUS.STOP[1]=1 at any time and wait rx_done interrupt; final disable FlexBUS;
J. If want to continue to receive data, repeat G-H-I.

DAC Transfer Flow
If want to support DAC feature, the configuration is showing as below:
A. Set modes, tx only, FLEXBUS_COM_CTL[3:0]=4'h1;
B. Set Interrupt mask, FLEXBUS_IMR;
C. Set format of transmit data, FLEXBUS_TX_CTL and continue_mode =1;
D. Set tx start water line, FLEXBUS_TXWAT_START;
E. Set DMA;
F. Set FlexBUS enable, FLEXBUS_ENR[1:0]=2'b01;
G. Wait interrupt, if dma_src0 is active indicating that buffer0 has finished and clear interrupt, FlexBUS can set new buffer0 address. FlexBUS will automatically jump to buffer1 address and send new data; If don't want to send data, set FLEXBUS_STOP[0]=1, and then disable FlexBUS;
H. Wait interrupt, if dma_src1 is active indicating that buffer1 has finished and clear interrupt, FlexBUS can set new buffer1 address. FlexBUS will automatically jump to buffer0 address and send new data; If don't want to send new data, Set FLEXBUS_STOP[0]=1, and then disable FlexBUS;
I. If want to stop sending data , set FlexBUS.STOP[0]=1 at any time and wait tx_done

Rockchip Confidential

interrupt; final disable FlexBUS;
J. If want to continue to receive data, repeat G-H-I.

DVP Mode Transfer Flow
A. Set GRF_SOC_CON1[1] based on cif interface timing and set GRF_SOC_CON1[1]=0 to as slave;
B. Set modes, rx only mode, FLEXBUS_COM_CTL[3:0]=4'h2;
C. Set Interrupt mask, FLEXBUS_IMR;
D. Set format of receive data, FLEXBUS_RX_CTL.rx_data_width=2 and rx_continue_mode=1;
E. Set FLEXBUS_SLAVE_MODE=2'b11;
F. Set FLEXBUS_DVP_CROP_SIZE, if want to support cropping function, need to Set FLEXBUS_DVP_CROP_START.
G. Set FLEXBUS_DVP_POL based on CIF interface of VSYNC and HREF;
H. Set FLEXBUS_DVP_ORDER and DMA, FLEXBUS_DMA_DST_ADD0/1, used to ping-pang operation;
I. Set FlexBUS enable, FLEXBUS_ENR[1]=1'b1;
J. Wait interrupt, if dma_dst0 is active indicating that a frame has finished and clear interrupt, FlexBUS can set new buffer0 address. FlexBUS will automatically jump to buffer1 address and capture new frame; If dvp_frame_ab is active, need to clear interrupt and FlexBUS will automatically continue to capture the next frame using buffer0 address; If don't want to receive new frame, Set FLEXBUS_STOP[1]=1, and then disable FlexBUS;
K. Wait interrupt, if dma_dst1 is active indicating that a frame has finished and clear interrupt, FlexBUS can set new buffer1 address. FlexBUS will automatically jump to buffer0 address and capture new frame; If dvp_frame_ab is active, need to clear interrupt and FlexBUS will automatically continue to capture the next frame using buffer1 address; If don't want to receive new frame, Set FLEXBUS_STOP[1]=1, and then disable FlexBUS;
L. If want to receive new frame pixel, repeat J-K.

QSPI Transfer Flow
If want to support QSPI feature, the configuration is showing as below:
A. Set modes, tx only, FLEXBUS_COM_CTL[3:0]=4'h1;
B. Set Interrupt mask, FLEXBUS_IMR;
C. Set format of transmit data, FLEXBUS_TX_CTL.mult_line =1;
D. Set tx start water line, FLEXBUS_TXWAT_START;
E. Set the length of data and command, FLEXBUS_TX_NUM, FLEXBUS_TX_CMD0/1, FLEXBUS_TX_CMD_WIDTH, FLEXBUS_TX_CSN_DUMMY, FLEXBUS_TX_WIDTH;
F. Set DMA configuration;
G. Set FlexBUS enable, FLEXBUS_ENR[0]=1'b1;
H. Wait tx_done interrupt and clear interrupt, disable FlexBUS.

Rockchip Confidential

Chapter 38 MAC Ethernet Interface (MAC)

38.1 Overview

The Ethernet Quality-of-Service controller (EQOS is commonly referred to as MAC in this document) provides a complete Ethernet interface from processor to a Reduced Media Independent Interface (RMII) compliant Ethernet PHY. The MAC includes a DMA controller. The DMA controller efficiently moves packet data from microprocessor's RAM, formats the data for an IEEE 802.3-2002 compliant packet and transmits the data to an Ethernet Physical Interface (PHY). It also efficiently moves packet data from RXFIFO to microprocessor's RAM.
The following features may or may not be present in the actual product. Please contact Rockchip for the actual feature configurations and the third-party licensing requirements.

38.1.1 MAC Features

38.1.1.1 MAC Tx and Rx Common Features

- Supports 10/100-Mbps data transfer rates with the RMII interfaces
- Half-duplex operation:
  - CSMA/CD Protocol support
  - Flow control using back-pressure support (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
- 64-bit data transfer interface on the application side
- Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
- network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Media clock generation and recovery
- MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

38.1.1.2 MAC Tx Features

- Preamble and start of packet data (SFD) insertion
- Separate 32-bit status for each packet transmitted from the application
- Automatic CRC and pad generation controllable on a per-packet basis
- Programmable Inter Packet Gap (40–96 bit times in steps of 8)
- IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in full-duplex mode)
- Source Address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement, or deletion of up to two VLAN tags
- Frame Preemption for MAC Tx

38.1.1.3 MAC Rx Features

- Automatic Pad and CRC Stripping options
- Option to disable Automatic CRC checking
- Preamble and SFD deletion
- Separate 112-bit or 128-bit status
- Programmable watchdog timeout limit
- Flexible address filtering modes:
  - Up to 31 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 96 additional 48-bit perfect (DA) address filters that can be selected in blocks of 32 and 64 registers
  - Up to 31 48-bit SA address comparison check with masks for each byte
  - 32 bit, 64 bit, 128 bit, or 256 bit Hash filter (optional) for multicast and unicast (DA) addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report

Rockchip Confidential

- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based (optional) filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering 4, 8, 16, or 32 filter selection
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- Optional module to detect remote wake-up packets and AMD magic packets
- Optional forwarding of received Pause packets to the application (in full-duplex mode)
- Frame Preemption for MAC Rx

38.1.2 MTL Features

38.1.2.1 MTL Tx and Rx Common Features

- 32-bit, 64-bit, or 128-bit Transaction Layer block (bridges the application and the MAC)
- Data transfers executed using simple FIFO protocol
- Synchronization for all clocks in the design (Transmit, Receive, and Application clocks)
- Optimization for packet-oriented transfers with packets delimiters
- Option to have dual-port RAM based asynchronous FIFO controllers or Single-port RAM based synchronous FIFO controllers
- RAM memory instantiation outside the top-level module to facilitate memory testing or instantiation
- Programmable burst length, up to half the size of the MTL Rx queue or Tx queue size, to support burst data transfer in the EQOS-MTL configuration
- Programmable threshold capability for each queue (default of 64 bytes)
- Optional Debug and slave mode operation on Queue 0 (default queue)

38.1.2.2 MTL Tx Features

- TX FIFO sizes on transmission is 4 KB
- Store-and-Forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Programmable queue size in configurations with multiple queues. Each queue size can be programmed in terms of 256 bytes
- Automatic re-transmission of collision packets in half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Disabling of Data Memory RAM chip-select when inactive to reduce power consumption
- Optional module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum
- Programmable interrupt options for different operational conditions
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Optional packet-level control for
  - VLAN tag insertion or replacement
  - Ethernet source address insertion
  - Layer3/Layer4 Checksum insertion control
  - Timestamp control
  - CRC and pad control

38.1.2.3 MTL Rx Features

- Rx queue sizes in the Receive path is 8 KB
- Insertion of Rx Status vectors into the Rx queue after the EOP transfer (in Threshold mode) and before SOP (in Store-and-Forward mode) in EQOS-MTL configuration
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx

Rockchip Confidential

FIFO

- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level
- Arbitration among queues when multiple queues are present. The following arbitration schemes are supported:
  - Weighted Round Robin (WRR)
  - Weighted Strict priority (WSP)
  - Strict Priority (SP)
- Option to replicate received multicast packets for transfer by multiple Rx DMA channels
- Option to have a programmable lookup table based flexible Parser for filtering and steering the Rx packets

38.1.3 DMA Block Features

- 64-bit data transfers
- Separate DMA channel in the Transmit path for each queue in MTL
- Single or multiple DMA channels for any number of queues in MTL Receive path
- Fully synchronous design operating on a single application clock (except for CSR module, when a separate CSR clock is configured)
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture to allow large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 KB of data)
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host CSR access and host data interface
- support for TCP Segmentation Offload (TSO) and UDP Segmentation Offload (USO)
- Selectable number of Tx DMA channels with TSO/USO feature enabled
- Routing of received packets to the DMA channels based on the DA or VLAN Priority in multi-channel DMA configurations
- Option to split the packet header (Layer 3 and Layer 4) and payload in a different buffers
- Programmable control for Transmit Descriptor posted writes to improve the throughput
- Sideband signals to control starting and stopping of DMA channels

38.2 Block Diagram

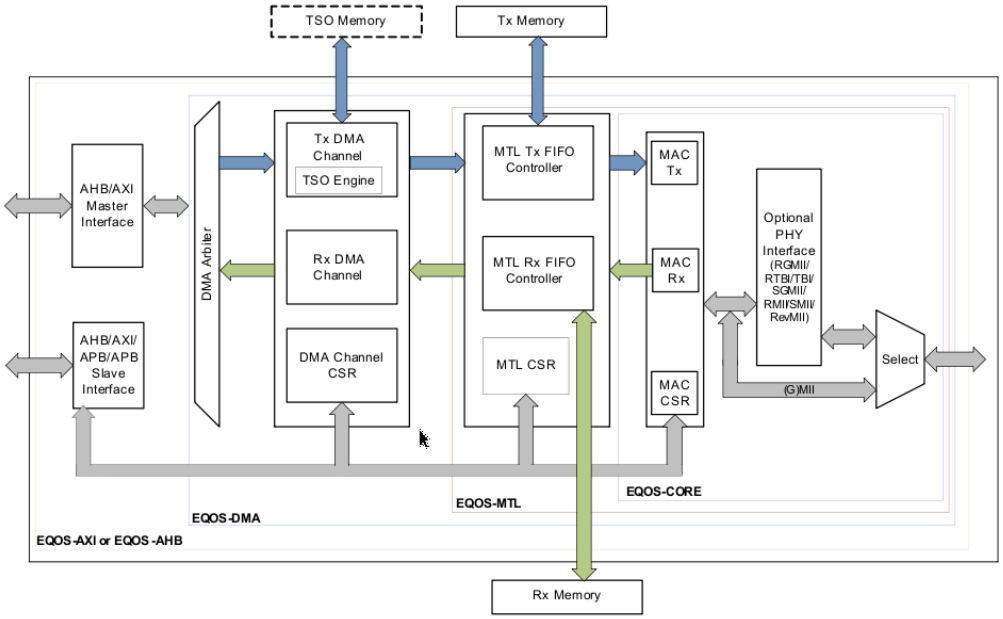

Fig. 38-1 MAC Block Diagram

The MAC is broken up into multiple separate functional units. These blocks are interconnected in the MAC module. The block diagram shows the general flow of data and control signals between these blocks.
The MAC transfers data to system memory through the AXI master interface. The host CPU uses the APB Slave interface to access the MAC subsystem's control and status registers (CSRs).
The MAC only supports the PHY interfaces of reduced MII (RMII).
The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the MAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by the DMA. These are asynchronous FIFOs, as they also transfer the data between the application clock and the MAC line clocks.

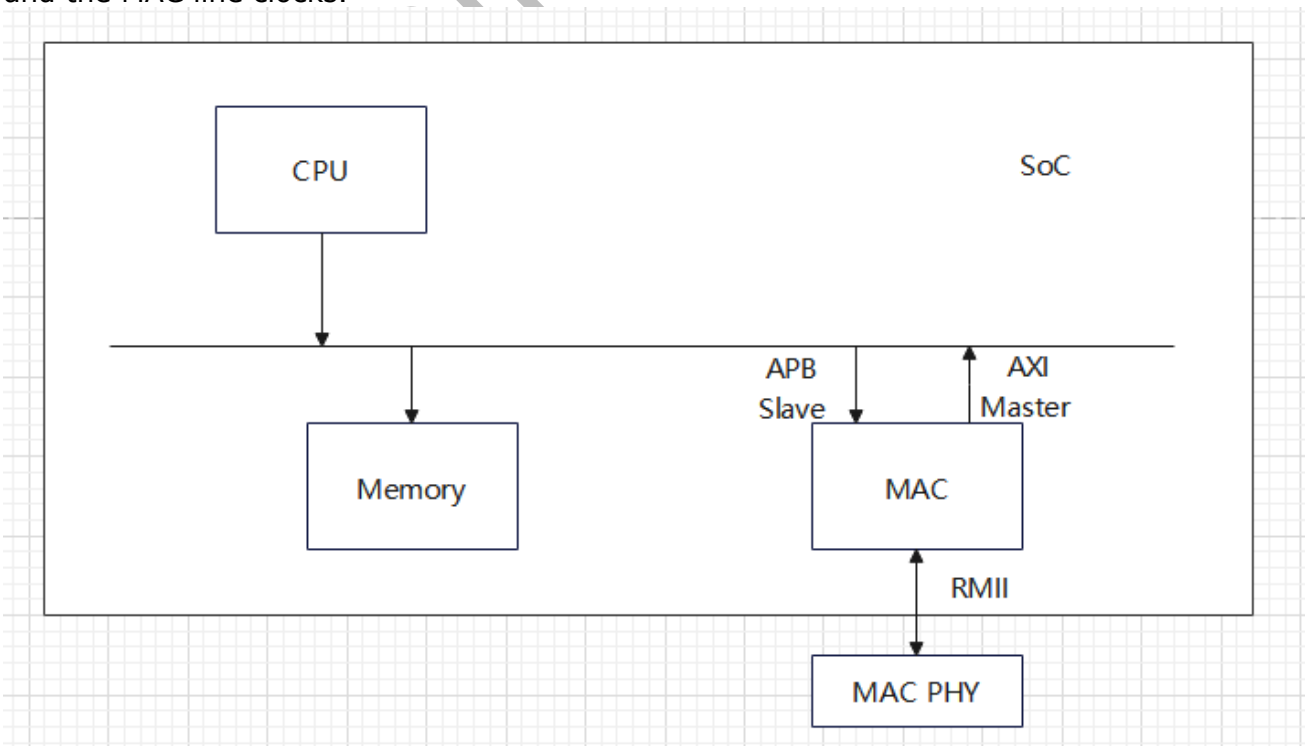

Fig. 38-2 MAC in SOC

Rockchip Confidential

MAC Supports 10/100-Mbps data transfer rates with the RMII interfaces.

38.3 Function Description

38.3.1 Frame Structure

Data frames transmitted shall have the frame format shown in figure below.

Fig. 38-3 Frame Format

The preamble <preamble> begins a frame transmission. The bit value of the preamble field consists of 7 octets with the following bit values:
10101010 10101010 10101010 10101010 10101010 10101010 10101010
The SFD (start frame delimiter) <sfd> indicates the start of a frame and follows the preamble. The bit value is 10101011.The data in a well formed frame shall consist of N octet's data.

38.3.1.1 RMII Interface timing diagram

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode). According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port - a 62.5% decrease in pin count.
The RMII module is instantiated between the MAC and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:
Supports 10-Mbps and 100-Mbps operating rates. It does not support 1000-Mbps operation. Two clock references are sourced externally or CRU, providing independent, 2-bit wide transmit and receive paths.

38.3.1.2 Transmit Bit Ordering

Each nibble from the MII must be transmitted on the RMII a di-bit at a time with the order of di-bit transmission shown in Fig.1-4. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

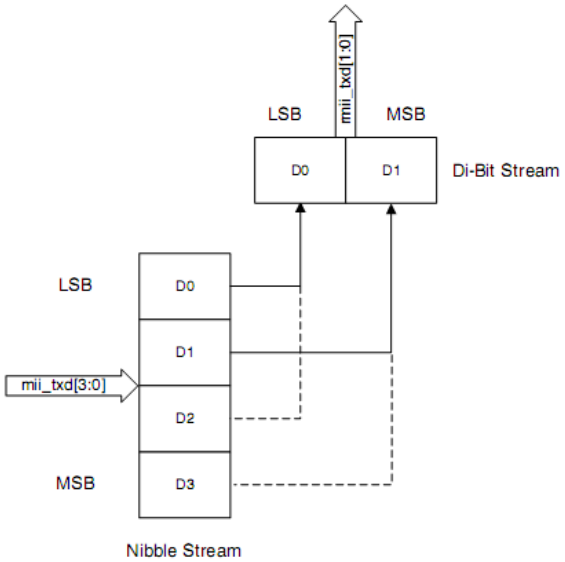

Fig. 38-4 RMII Transmission Bit Ordering

38.3.1.3 RMII Transmit Timing Diagrams

The follow figures show MII-to-RMII transaction timing. The clk_rmii_i (REF_CLK) frequency is 50MHz in RMII interface. In 10Mb/s mode, as the REF_CLK frequency is 10 times as the data rate, the value on rmii_txd_o[1:0] (TXD[1:0]) shall be valid such that TXD[1:0] may be sampled every 10th cycle, regard-less of the starting cycle within the

Rockchip Confidential

group and yield the correct frame data.

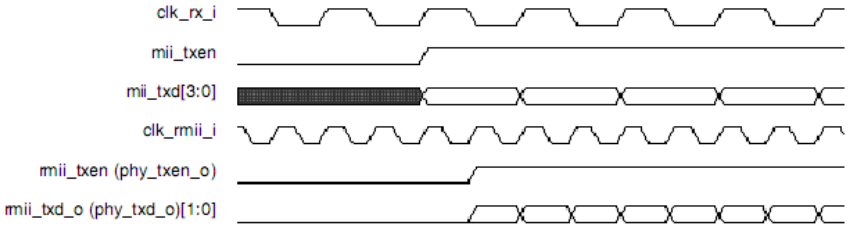

Fig. 38-5 Start of MII and RMII Transmission in 100-Mbps Mode

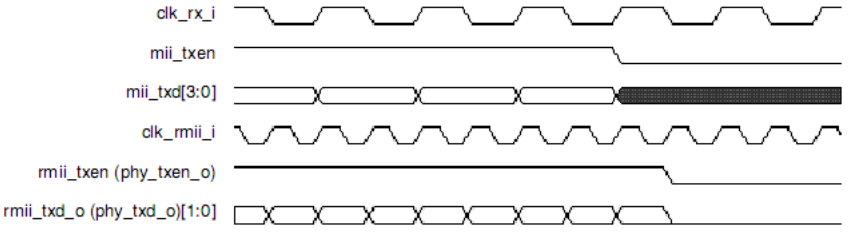

Fig. 38-6 End of MII and RMII Transmission in 100-Mbps Mode

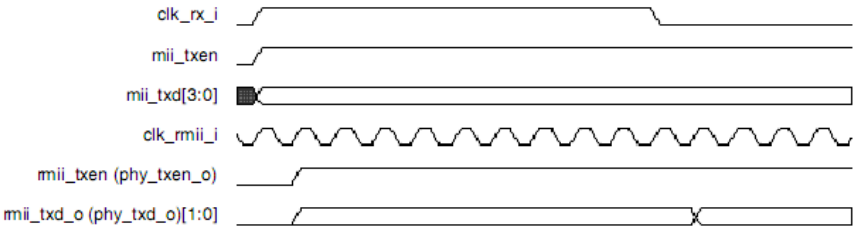

Fig. 38-7 Start of MII and RMII Transmission in 10-Mbps Mode

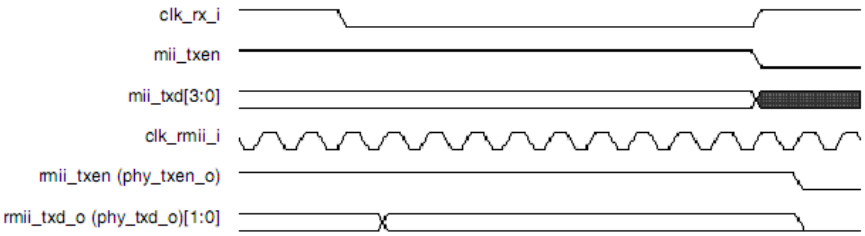

Fig. 38-8 End of MII and RMII Transmission in 10-Mbps Mode

38.3.1.4 Receive Bit Ordering

Each nibble is transmitted to the MII from the di-bit received from the RMII in the nibble transmission order shown in figure below. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Rockchip Confidential

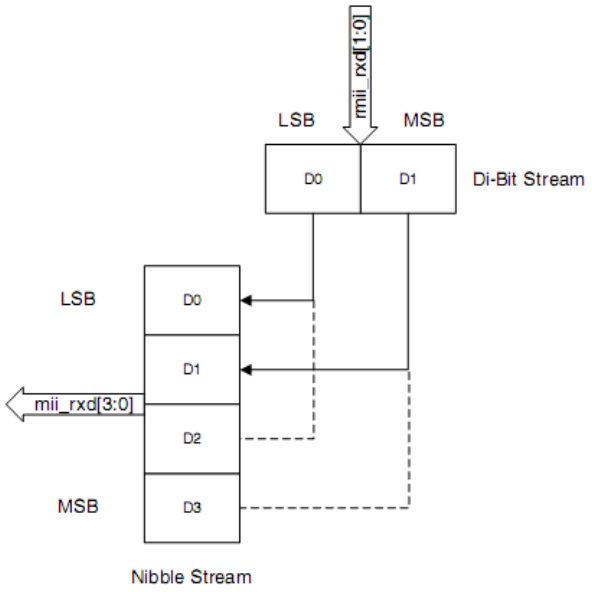

Fig. 38-9 RMII Receive Bit Ordering

38.3.2 Station Management Agent

The application can access the PHY registers through the Station Management Agent (SMA) module. SMA is a two-wire Station Management interface (MIM).

For MIM accesses, the maximum operating frequency of the MDC (gmii_mdc_o) is 2.5 MHz, as specified in the IEEE 802.3. In the MAC core, the gmii_mdc_o clock is derived from the application clock or clk_csr_i, using a divider-counter. The divide factor depends on the clock range setting (CR field) in the MAC_MDIO_Address register Select the clock divide factor as mentioned in the description of CR field of MAC_MDIO_Address register, to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIM interface, there is a provision to select a different divider.

The MDIO frame structure is as follows:

Table 38-1 MDIO Clause 45 Frame Structure

Field	Description
IDLE	The mdio line is in tri-state; there is no clock on gmii_mdc_o signal.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2'b00
OPCODE	■ 2'b00 ■ 2'b01 ■ 2'b10 ■ 2'b11
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address select for one of 32 devices
TA	Turnaround ■ 2'bZ0: Read and post-read increment address ■ 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	16-bit value: For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. ■ In address and data write cycles, the MAC drives the MDIO line during the transfer of these 16 bits. ■ In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits.

Rockchip Confidential

The frame structure for Clause 22 frames is also supported. The C45E bit in the MAC_MDIO_Address register can be programmed to enable Clause 22 or Clause 45 mode of operation. Table.1-2 shows the Clause 22 frame format.

Table 38-2 MDIO Clause 22 Frame Structure

Field	Description
IDLE	The mdio line is in tri-state; there is no clock on gmii_mdc_o signal.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2'b01
OPCODE	■ 2'b01 : Write ■ 2'b10 : Read
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address to select the register within each MMD
TA	Turnaround ■ 2'bZ0: Read and post-read increment address ■ 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	Any 16-bit value: ■ In a write operation, the MAC drives MDIO ■ In read operation, the PHY drives MDIO

In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

38.3.3 TCP/IP Segmentation Offload (TSO) Engine

The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

It also supports UDP Segmentation Offload (USO) in which the UDP payload is segmented in the hardware. There are no sequencing/ordering controls available or updated in the segments, so it can be used in point to point applications in which out of order packets are not expected by the receiver. The description and flow of TSO mentioned in this section is same as USO, any deviation is provided as notes.

In the TCP segmentation offload (TSO) feature, the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL Tx Queue.

38.3.4 MAC Management Counters

The MAC supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two status registers containing interrupts generated (receive and transmit), and Interrupt Enable registers (receive and transmit). These registers are accessible from the Application through the MAC Control Interface (MCI). Each register is 32-bits wide. The write data is qualified with the corresponding mci_be_i signals. Therefore, non-32-bit accesses are allowed as long as the address is word-aligned. The MMCs are accessed using transactions, in the same way the CSR address space is accessed.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present in the RTL, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set Bit 0 in the "MAC_Packet_Filter" register.

Rockchip Confidential

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

38.4 Register Description

38.4.1 Internal Address Mapping

Slave address can be divided into different length for different usage, which is shown as follows.

Operational Base

Name	Base Address
MAC0	0xFF4C8000
MAC1	0xFF4D0000

38.4.2 Registers Summary

Name	Offset	Size	Reset Value	Description
GMAC_MAC_CONFIGURATION	0x0000	W	0x00008000	The MAC Configuration Register establishes the operating mode of the MAC
GMAC_MAC_EXT_CONFIGURATION	0x0004	W	0x00000000	The MAC Extended Configuration Register establishes the operating mode of the MAC
GMAC_MAC_PACKET_FILTER	0x0008	W	0x00000000	The MAC Packet Filter Register contains the filter controls for receiving packets
GMAC_MAC_WATCHDOG_TIMEOUT	0x000C	W	0x00000000	The Watchdog Timeout Register controls the watchdog timeout for received packets
GMAC_MAC_HASH_TABLE_REG0	0x0010	W	0x00000000	The Hash Table Register 0 contains the first 32 bits of the hash table
GMAC_MAC_HASH_TABLE_REG1	0x0014	W	0x00000000	The Hash Table Register 1 contains the second 32 bits of the hash table
GMAC_MAC_VLAN_TAG	0x0050	W	0x00000000	The VLAN Tag Register identifies the IEEE 802.1Q VLAN type packets
GMAC_MAC_VLAN_HASH_TABLE	0x0058	W	0x00000000	When VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag
GMAC_MAC_Q0_TX_FLOW_CTRL	0x0070	W	0x00000000	The Flow Control Register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC
GMAC_MAC_RX_FLOW_CTRL	0x0090	W	0x00000000	The Receive Flow Control Register controls the pausing of MAC Transmit based on the received Pause packet
GMAC_MAC_INTERRUPT_STATUS	0x00B0	W	0x00000000	The Interrupt Status Register contains the status of interrupts
GMAC_MAC_INTERRUPT_ENABLE	0x00B4	W	0x00000000	The Interrupt Enable Register contains the masks for generating the interrupts

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
GMAC_MAC_RX_TX_STATUS	0x00B8	W	0x00000000	The Receive Transmit Status Register contains the Receive and Transmit Error status
GMAC_MAC_PMT_CONTROL_STATUS	0x00C0	W	0x00000000	The PMT Control and Status Register
GMAC_MAC_RWK_PACKET_FILTER	0x00C4	W	0x00000000	The Remote Wakeup Filter Registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_Packet_Filter register
GMAC_RWK_FILTER0_BYTE_MASK	0x00C4	W	0x00000000	RWK Filter0 Byte Mask
GMAC_RWK_FILTER1_BYTE_MASK	0x00C4	W	0x00000000	RWK Filter1 Byte Mask
GMAC_RWK_FILTER2_BYTE_MASK	0x00C4	W	0x00000000	RWK Filter2 Byte Mask
GMAC_RWK_FILTER3_BYTE_MASK	0x00C4	W	0x00000000	RWK Filter3 Byte Mask
GMAC_RWK_FILTER01_CRC	0x00C4	W	0x00000000	RWK Filter 0/1 CRC-16
GMAC_RWK_FILTER23_CRC	0x00C4	W	0x00000000	RWK Filter 2/3 CRC-16
GMAC_RWK_FILTER_OFFSET	0x00C4	W	0x00000000	RWK Filter Offset
GMAC_RWK_FILTER_COMMAND	0x00C4	W	0x00000000	RWK Filter Command
GMAC_MAC_VERSION	0x0110	W	0x00003051	The Version Register identifies the version of the DWC_ether_qos
GMAC_MAC_DEBUG	0x0114	W	0x00000000	The Debug Register provides the debug status of various MAC blocks
GMAC_MAC_HW_FEATURE0	0x011C	W	0x400113E1	This register indicates the presence of first set of the optional features or functions
GMAC_MAC_HW_FEATURE1	0x0120	W	0x010E4166	This register indicates the presence of second set of the optional features or functions
GMAC_MAC_HW_FEATURE2	0x0124	W	0x11000000	This register indicates the presence of third set of the optional features or functions
GMAC_MAC_HW_FEATURE3	0x0128	W	0x00000000	This register indicates the presence of fourth set the optional features or functions
GMAC_MAC_MDIO_ADDRESS	0x0200	W	0x00000000	The MDIO Address Register controls the management cycles to external PHY through a management interface

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
GMAC_MAC_MDIO_DATA	0x0204	W	0x00000000	The MDIO Data Register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address
GMAC_MAC_ARP_ADDRESS	0x0210	W	0x00000000	The ARP Address Register contains the IPv4 Destination Address of the MAC
GMAC_MAC_CSR_SW_CTRL	0x0230	W	0x00000000	This register contains SW programmable controls for changing the CSR access response and status bits clearing
GMAC_MAC_EXT_CFG1	0x0238	W	0x00000002	This register contains Split mode control field and offset field for Split Header feature
GMAC_MAC_ADDRESS0_HIGH	0x0300	W	0x0000FFFF	The MAC Address0 High Register holds the upper 16 bits of the first 6-byte MAC address of the station
GMAC_MAC_ADDRESS0_LOW	0x0304	W	0xFFFFFFFF	The MAC Address0 Low Register holds the lower 32 bits of the 6-byte first MAC address of the station
GMAC_MMC_CONTROL	0x0700	W	0x00000000	This register establishes the operating mode of MMC
GMAC_MMC_RX_INTERRUPT	0x0704	W	0x00000000	This register maintains the interrupts generated from all Receive statistics counters
GMAC_MMC_TX_INTERRUPT	0x0708	W	0x00000000	This register maintains the interrupts generated from all Transmit statistics counters
GMAC_MMC_RX_INTERRUPT_MASK	0x070C	W	0x00000000	This register maintains the masks for interrupts generated from all Receive statistics counters
GMAC_MMC_TX_INTERRUPT_MASK	0x0710	W	0x00000000	This register maintains the masks for interrupts generated from all Transmit statistics counters
GMAC_TX_OCTET_COUNT_GOOD_BAD	0x0714	W	0x00000000	This register provides the number of bytes transmitted by the DWC_ether_qos, exclusive of preamble and retried bytes, in good and bad packets
GMAC_TX_PACKET_COUNT_GOOD_BAD	0x0718	W	0x00000000	This register provides the number of good and bad packets, exclusive of retried packets
GMAC_TX_UNDERFLOW_ERROR_PACKETS	0x0748	W	0x00000000	This register provides the number of packets aborted because of packets underflow error
GMAC_TX_CARRIER_ERROR_PACKETS	0x0760	W	0x00000000	This register provides the number of packets aborted because of carrier sense error (no carrier or loss of carrier)
GMAC_TX_OCTET_COUNT_GOOD	0x0764	W	0x00000000	This register provides the number of bytes exclusive of preamble, only in good packets

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
GMAC_TX_PACKET_COUNT_GOOD	0x0768	W	0x00000000	This register provides the number of good packets transmitted by DWC_ether_qos
GMAC_TX_PAUSE_PACKETS	0x0770	W	0x00000000	This register provides the number of good Pause packets by DWC_ether_qos
GMAC_RX_PACKETS_COUNT_GOOD_BAD	0x0780	W	0x00000000	This register provides the number of good and bad packets received by DWC_ether_qos
GMAC_RX_OCTET_COUNT_GOOD_BAD	0x0784	W	0x00000000	This register provides the number of bytes received by DWC_ether_qos, exclusive of preamble, in good and bad packets
GMAC_RX_OCTET_COUNT_GOOD	0x0788	W	0x00000000	This register provides the number of bytes received by DWC_ether_qos, exclusive of preamble, only in good packets
GMAC_RX_MULTICAST_PACKETS_GOOD	0x0790	W	0x00000000	This register provides the number of good multicast packets received by DWC_ether_qos
GMAC_RX_CRC_ERROR_PACKETS	0x0794	W	0x00000000	This register provides the number of packets received by DWC_ether_qos with CRC error
GMAC_RX_LENGTH_ERROR_PACKETS	0x07C8	W	0x00000000	This register provides the number of packets received by DWC_ether_qos with length error (Length Type field not equal to packet size), for all packets with valid length field
GMAC_RX_PAUSE_PACKETS	0x07D0	W	0x00000000	This register provides the number of good and valid Pause packets received by DWC_ether_qos
GMAC_RX_FIFO_OVERFLOW_PACKETS	0x07D4	W	0x00000000	This register provides the number of missed received packets because of FIFO overflow
GMAC_MMC_IPC_RX_INTERRUPT_MASK	0x0800	W	0x00000000	This register maintains the mask for the interrupt generated from the receive IPC statistic counters
GMAC_MMC_IPC_RX_INTERRUPT	0x0808	W	0x00000000	This register maintains the interrupt that the receive IPC statistic counters generate
GMAC_RXIPV4_GOOD_PACKETS	0x0810	W	0x00000000	This register provides the number of good IPv4 datagrams received by DWC_ether_qos with the TCP, UDP, or ICMP payload
GMAC_RXIPV4_HEADER_ERROR_PACKETS	0x0814	W	0x00000000	This register provides the number of IPv4 datagrams received by DWC_ether_qos with header (checksum, length, or version mismatch) errors
GMAC_RXIPV6_GOOD_PACKETS	0x0824	W	0x00000000	This register provides the number of good IPv6 datagrams received by DWC_ether_qos

Rockchip Confidential

GMAC_MAC_SYS_TIME_NS_UPDATE	0x0B14	W	0x00000000	MAC System Time Nanoseconds Update Register
GMAC_MAC_TIMESTAMP_ADDEND	0x0B18	W	0x00000000	Timestamp Addend Register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register)
GMAC_MAC_TIMESTAMP_STATUS	0x0B20	W	0x00000000	Timestamp Status Register. All bits except Bits[27:25] gets cleared when the application reads this register
GMAC_MAC_TX_TS_STATUS_NS	0x0B30	W	0x00000000	This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled
GMAC_MAC_TX_TS_STATUS_SECS	0x0B34	W	0x00000000	The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted
GMAC_MAC_AUXILIARY_CONTROL	0x0B40	W	0x00000000	The Auxiliary Timestamp Control Register controls the Auxiliary Timestamp snapshot
GMAC_MAC_AUXILIARY_TS_NS	0x0B48	W	0x00000000	The Auxiliary Timestamp Nanoseconds Register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot
GMAC_MAC_AUXILIARY_TS_SECS	0x0B4C	W	0x00000000	The Auxiliary Timestamp Seconds Register contains the lower 32 bits of the Seconds field of the auxiliary timestamp register
GMAC_MAC_TS_INGRESS_CORR_NS	0x0B58	W	0x00000000	This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path
GMAC_MAC_TS_EGRESS_CORR_NS	0x0B5C	W	0x00000000	This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path
GMAC_MAC_TS_INGRESS_LATENCY	0x0B68	W	0x00000000	This register holds the Ingress MAC latency

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
GMAC_MAC_TS_EGRESS_LATENCY	0x0B6C	W	0x00000000	This register holds the Egress MAC latency
GMAC_MAC_PPS_CONTROL	0x0B70	W	0x00000000	PPS Control Register
GMAC_MAC_PPS0_TARGET_TIME_SECONDS	0x0B80	W	0x00000000	The PPS Target Time Seconds Register, along with PPS Target Time Nanoseconds Register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers
GMAC_MAC_PPS0_TARGET_TIME_NS	0x0B84	W	0x00000000	PPS0 Target Time Nanoseconds Register
GMAC_MAC_PPS0_INTERVAL	0x0B88	W	0x00000000	The PPS0 Interval Register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0])
GMAC_MAC_PPS0_WIDTH	0x0B8C	W	0x00000000	The PPS0 Width Register contains the number of units of sub-second increment value
GMAC_MTL_OPERATION_MODE	0x0C00	W	0x00000000	The Operation Mode Register establishes the Transmit and Receive operating modes and commands
GMAC_MTL_DBG_CTL	0x0C08	W	0x00000000	The FIFO Debug Access Control and Status Register controls the operation mode of FIFO debug access
GMAC_MTL_DBG_STS	0x0C0C	W	0x01000000	The FIFO Debug Status Register contains the status of FIFO debug access
GMAC_MTL_FIFO_DEBUG_DATA	0x0C10	W	0x00000000	The FIFO Debug Data Register contains the data to be written to or read from the FIFOs
GMAC_MTL_INTERRUPT_STATUS	0x0C20	W	0x00000000	The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC
GMAC_MTL_TXQ0_OPERATION_MODE	0x0D00	W	0x00000000	The Queue 0 Transmit Operation Mode Register establishes the Transmit queue operating modes and commands
GMAC_MTL_TXQ0_UNDERFLOW	0x0D04	W	0x00000000	The Queue 0 Underflow Counter Register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
GMAC_MTL_TXQ0_DEBUG	0x0D08	W	0x00000000	The Queue 0 Transmit Debug Register gives the debug status of various blocks related to the Transmit queue
GMAC_MTL_Q0_INTERRUPT_CTRL_STATUS	0x0D2C	W	0x00000000	This register contains the interrupt enable and status bits for the queue 0 interrupts
GMAC_MTL_RXQ0_OPERATION_MODE	0x0D30	W	0x00000000	The Queue 0 Receive Operation Mode Register establishes the Receive queue operating modes and command
GMAC_MTL_RXQ0_MISS_PKT_OVF_CNT	0x0D34	W	0x00000000	The Queue 0 Missed Packet and Overflow Counter Register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow
GMAC_MTL_RXQ0_DEBUG	0x0D38	W	0x00000000	The Queue 0 Receive Debug Register gives the debug status of various blocks related to the Receive queue
GMAC_DMA_MODE	0x1000	W	0x00000000	The Bus Mode Register establishes the bus operating modes for the DMA
GMAC_DMA_SYSBUS_MODE	0x1004	W	0x00010000	The System Bus mode Register controls the behavior of the AHB or AXI master
GMAC_DMA_INTERRUPT_STATUS	0x1008	W	0x00000000	The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC
GMAC_DMA_DEBUG_STATUS0	0x100C	W	0x00000000	The Debug Status 0 Register gives the Receive and Transmit process status for DMA Channel 0-Channel 2 for debugging purpose
GMAC_AXI_LPI_ENTRY_INTERVAL	0x1040	W	0x00000000	This register is used to control the AXI LPI entry interval
GMAC_DMA_CH0_CONTROL	0x1100	W	0x00000000	The register specifies the MSS value for segmentation, length to skip between two descriptors, and 8xPBL mode
GMAC_DMA_CH0_TX_CONTROL	0x1104	W	0x00000000	The register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights
GMAC_DMA_CH0_RX_CONTROL	0x1108	W	0x00000000	The DMA Channel0 Receive Control Register controls the Rx features such as PBL, buffer size, and extended status

38.4.3 Detail Registers Description

GMAC_MAC_CONFIGURATION

Address: **Operational Base** + offset (0x0000)

Bit	Attr	Reset Value	Description
31	RW	0x0	ARPEN ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus. This bit is available only when the Enable IPv4 ARP Offload is selected. Values: 1'b0: ARP Offload is disabled 1'b1: ARP Offload is enabled
30:28	RO	0x0	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
27	RW	0x0	IPC Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. Values: 1'b0: IP header/payload checksum checking is disabled 1'b1: IP header/payload checksum checking is enabled
26:24	RW	0x0	IPG Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. Values: 3'b000: 96 bit times IPG 3'b001: 88 bit times IPG 3'b010: 80 bit times IPG 3'b011: 72 bit times IPG 3'b100: 64 bit times IPG 3'b101: 56 bit times IPG 3'b110: 48 bit times IPG 3'b111: 40 bit times IPG
23	RW	0x0	GPSLCE Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. Values: 1'b0: Giant Packet Size Limit Control is disabled 1'b1: Giant Packet Size Limit Control is enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
22	RW	0x0	S2KP IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. Values: 1'b0: Support up to 2K packet is disabled 1'b1: Support up to 2K packet is Enabled
21	RW	0x0	CST CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. Values: 1'b0: CRC stripping for Type packets is disabled 1'b1: CRC stripping for Type packets is enabled
20	RW	0x0	ACS Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit. Values: 1'b0: Automatic Pad or CRC Stripping is disabled 1'b1: Automatic Pad or CRC Stripping is enabled
19	RW	0x0	WD Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. Values: 1'b0: Watchdog is enabled 1'b1: Watchdog is disabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
18	RW	0x0	BE Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. Values: 0x0 (DISABLE): Packet Burst is disabled 0x1 (ENABLE): Packet Burst is enabled Value After Reset: 0x0
17	RW	0x0	JD Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data(10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. Values: 0x0 (ENABLE): Jabber is enabled 0x1 (DISABLE): Jabber is disabled Value After Reset: 0x0 Exists: Always
16	RW	0x0	JE Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. Values: 1'b0: Jumbo packet is disabled 1'b1: Jumbo packet is enabled
15	RW	0x1	PS Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. Values: 1'b0: For 1000 or 2500 Mbps operations 1'b1: For 10 or 100 Mbps operations
14	RW	0x0	FES Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. Values: 0x0 (10_1000M): 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 0x1 (100_2500M): 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13	RW	0x0	DM Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. Values: 1'b0: Half-duplex mode 1'b1: Full-duplex mode

Rockchip Confidential

Bit	Attr	Reset Value	Description
12	RW	0x0	LM Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. Values: 1'b0: Loopback is disabled 1'b1: Loopback is enabled
11:10	RO	0x0	reserved
9	RW	0x0	DCRS Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. Values: 1'b0: Enable Carrier Sense During Transmission 1'b1: Disable Carrier Sense During Transmission
8	RW	0x0	DR Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. Values: 1'b0: Enable Retry 1'b1: Disable Retry
7	RO	0x0	reserved
6:5	RW	0x0	BL Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. Values: 2'b00: k = min(n,10) 2'b01: k = min(n,8) 2'b10: k = min(n,4) 2'b11: k = min(n,1)

Rockchip Confidential

Bit	Attr	Reset Value	Description
4	RW	0x0	DC Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. Values: 1'b0: Deferral check function is disabled 1'b1: Deferral check function is enabled
3:2	RW	0x0	PRELEN Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. Values: 2'b00: 7 bytes of preamble 2'b01: 5 bytes of preamble 2'b10: 3 bytes of preamble 2'b11: Reserved
1	RW	0x0	TE Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled fortransmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. Values: 0x0 (DISABLE): Transmitter is disabled 0x1 (ENABLE): Transmitter is enabled Value After Reset: 0x0
0	RW	0x0	RE Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. Values: 1'b0: Receiver is disabled 1'b1: Receiver is enabled

GMAC_MAC_EXT_CONFIGURATION

Rockchip Confidential

Address: **Operational Base** + offset (0x0004)

Bit	Attr	Reset Value	Description
31:30	RO	0x0	reserved
29:25	RW	0x00	EIPG Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24	RW	0x0	EIPGEN Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. Values: 1'b0: Extended Inter-Packet Gap is disabled 1'b1: Extended Inter-Packet Gap is enabled
23	RO	0x0	reserved
22:20	RW	0x0	HDSMS Maximum Size for Splitting the Header Data These bits indicate the maximum header size allowed for splitting the header data in the received packet. Values: 0x0 (64BYTES): Maximum Size for Splitting the Header Data is 64 bytes 0x1 (128BYTES): Maximum Size for Splitting the Header Data is 128 bytes 0x2 (256BYTES): Maximum Size for Splitting the Header Data is 256 bytes 0x3 (512BYTES): Maximum Size for Splitting the Header Data is 512 bytes 0x4 (1024BYTES): Maximum Size for Splitting the Header Data is 1024 bytes 0x5 (RSVD): Reserved
19	RO	0x0	reserved
18	RW	0x0	USP Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5.

Rockchip Confidential

Bit	Attr	Reset Value	Description
			Values: 1'b0: Unicast Slow Protocol Packet Detection is disabled 1'b1: Unicast Slow Protocol Packet Detection is enabled
17	RW	0x0	SPEN Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. Values: 1'b0: Slow Protocol Detection is disabled 1'b1: Slow Protocol Detection is enabled
16	RW	0x0	DCRCC Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. Values: 1'b0: CRC Checking is enabled 1'b1: CRC Checking is disabled
15:14	RO	0x0	reserved
13:0	RW	0x0000	GPSL Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

GMAC_MAC_PACKET_FILTER

Address: **Operational Base** + offset (0x0008)

Bit	Attr	Reset Value	Description
31	RW	0x0	RA Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0x0 (DISABLE): Receive All is disabled 0x1 (ENABLE): Receive All is enabled
30:17	RO	0x0000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
16	RW	0x0	VTFE VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. Values: 1'b0: VLAN Tag Filter is disabled 1'b1: VLAN Tag Filter is enabled
15:11	RO	0x00	reserved
10	RW	0x0	HPF Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. Values: 1'b0: Hash or Perfect Filter is disabled 2'b1: Hash or Perfect Filter is enabled
9:8	RO	0x0	reserved
7:6	RW	0x0	PCF Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). Values: 2'b00: MAC filters all control packets from reaching the application 2'b01: MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 2'b10: MAC forwards all control packets to the application even if they fail the Address filter 2'b11: MAC forwards the control packets that pass the Address filter
5	RW	0x0	DBF Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. Values: 1'b0: Enable Broadcast Packets 1'b1: Disable Broadcast Packets
4	RW	0x0	PM Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. Values: 1'b0: Pass All Multicast is disabled 1'b1: Pass All Multicast is enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
3	RW	0x0	DAIF DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. Values: 1'b0: DA Inverse Filtering is disabled 1'b1: DA Inverse Filtering is enabled
2	RW	0x0	HMC Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. Values: 1'b0: Hash Multicast is disabled 1'b1: Hash Multicast is enabled
1:0	RO	0x0	reserved

GMAC_MAC_WATCHDOG_TIMEOUT

Address: **Operational Base** + offset (0x000C)

Bit	Attr	Reset Value	Description
31:9	RO	0x000000	reserved
8	RW	0x0	PWE Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register. Values: 1'b0: Programmable Watchdog is disabled 1'b1: Programmable Watchdog is enabled
7:4	RO	0x0	reserved
3:0	RW	0x0	WTO Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. Values: 4'b0000: 2 KB 4'b0001: 3 KB 4'b0010: 4 KB 4'b0011: 5 KB 4'b0100: 6 KB 4'b0101: 7 KB 4'b0110: 8 KB 4'b0111: 9 KB

GMAC_MAC_HASH_TABLE_REG0

Address: **Operational Base** + offset (0x0010)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	HT31T0 MAC Hash Table First 32 Bits This field contains the first 32 Bits [31:0] of the Hash table. The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

GMAC_MAC_HASH_TABLE_REG1

Address: **Operational Base** + offset (0x0014)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	HT63T32 MAC Hash Table Second 32 Bits This field contains the second 32 Bits [63:32] of the Hash table.

GMAC_MAC_VLAN_TAG

Address: **Operational Base** + offset (0x0050)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
24	RW	0x0	EVLRXS Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. Values: 1'b0: VLAN Tag in Rx status is disabled 1'b1: VLAN Tag in Rx status is enabled
23	RO	0x0	reserved
22:21	RW	0x0	EVLS Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. Values: 2'b00: Do not strip 2'b01: Strip if VLAN filter passes 2'b10: Strip if VLAN filter fails 2'b11: Always strip
20	RW	0x0	DOVLTC Disable VLAN Type Check When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit. Values: 1'b0: VLAN Type Check is enabled 1'b1: VLAN Type Check is disabled
19	RW	0x0	ERSVLM Enable Receive S-VLAN Match When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for filtering or matching. Values: 1'b0: Receive S-VLAN Match is disabled 1'b1: Receive S-VLAN Match is enabled
18	RW	0x0	ESVL Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. Values: 1'b0: S-VLAN is disabled 1'b1: S-VLAN is enabled
17	RW	0x0	VTIM VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. Values: 1'b0: VLAN Tag Inverse Match is disabled 1'b1: VLAN Tag Inverse Match is enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
16	RW	0x0	ETV Enable 12-Bit VLAN Tag Comparison When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN hash filtering. Values: 1'b0: 12-Bit VLAN Tag Comparison is disabled 1'b1: 12-Bit VLAN Tag Comparison is enabled
15:0	RW	0x0000	VL VLAN Tag Identifier for Receive Packets This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field: 1. Bits[15:13]: User Priority 2. Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) 3. Bits[11:0]: VLAN Identifier (VID) field of VLAN tag When the ETV bit is set, only the VID is used for comparison. If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.

GMAC_MAC_VLAN_HASH_TABLE

Address: **Operational Base** + offset (0x0058)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	VLHT VLAN Hash Table This field contains the 16-bit VLAN Hash Table. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. When ETV bit of MAC_VLAN_Tag register is set, the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. When ETV bit of MAC_VLAN_Tag register is reset, the ones-complement of upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, when ETV bit is set a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table, whereas when ETV bit is reset a hash value of 4b'1000 selects Bit 7 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3). 2. Perform bitwise reversal for the value obtained in step 1. 3. Take the upper four bits from the value obtained in step 2. If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. 1.If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

GMAC_MAC_Q0_TX_FLOW_CTRL

Address: **Operational Base** + offset (0x0070)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	PT Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15:8	RO	0x00	reserved
7	RW	0x0	DZPQ Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. Values: 1'b0: Zero-Quanta Pause packet generation is enabled 1'b1: Zero-Quanta Pause packet generation is disabled
6:2	RO	0x00	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
1	RW	0x0	TFE Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. Values: 1'b0: Transmit Flow Control is disabled 1'b1: Transmit Flow Control is enabled
0	RW	0x0	FCB_BPA Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Flow Control Busy or Backpressure Activate is disabled 1'b1: Flow Control Busy or Backpressure Activate is enabled

Bit	Attr	Reset Value	Description
31	RW	0x0	RWKFILTRST Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Remote Wake-Up Packet Filter Register Pointer is not Reset 1'b1: Remote Wake-Up Packet Filter Register Pointer is Reset
30:29	RO	0x0	reserved
28:24	RO	0x00	RWKPTR Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23:11	RO	0x0000	reserved
10	RW	0x0	RWKPFE Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Remote Wake-up Packet Forwarding is disabled 1'b1: Remote Wake-up Packet Forwarding is enabled
9	RW	0x0	GLBLUCAST Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. Values: 1'b0: Global unicast is disabled 1'b1: Global unicast is enabled
8:7	RO	0x0	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
6	RO	0x0	RWKPRCVD Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: 1'b0: Remote wake-up packet is received 1'b1: Remote wake-up packet is received
5	RO	0x0	MGKPRCVD Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: 1'b0: No Magic packet is received 1'b1: Magic packet is received
4:3	RO	0x0	reserved
2	RW	0x0	RWKPKTEN Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. Values: 1'b0: Remote wake-up packet is disabled 1'b1: Remote wake-up packet is enabled
1	RW	0x0	MGKPKTEN Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. Values: 1'b0: Magic Packet is disabled 1'b1: Magic Packet is enabled
0	RW	0x0	PWRDWN Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Power down is disabled 1'b1: Power down is enabled

GMAC_RWK_FILTER01_CRC

Address: **Operational Base** + offset (0x00C4)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	Filter1_CRC Filter1 CRC-16 This filter CRC-16 contains the CRC_16 value of the pattern. The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1
15:0	RW	0x0000	Filter0_CRC Filter0 CRC-16 This filter CRC-16 contains the CRC_16 value of the pattern. The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

GMAC_RWK_FILTER23_CRC

Address: **Operational Base** + offset (0x00C4)

Bit	Attr	Reset Value	Description
31:16	RW	0x0000	Filter3_CRC Filter3 CRC-16 This filter CRC-16 contains the CRC_16 value of the pattern. The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1
15:0	RW	0x0000	Filter2_CRC Filter2 CRC-16 This filter CRC-16 contains the CRC_16 value of the pattern. The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15+ x^2 + 1

GMAC_RWK_FILTER_OFFSET

Address: **Operational Base** + offset (0x00C4)

Bit	Attr	Reset Value	Description
31:24	RW	0x00	Filter3_Offset Filter3 Offset This filter offset defines the offset (within the packet) from which the filter examines the packets. 1. This 8-bit pattern-offset is the offset for the filter first byte to be examined. 2. The minimum allowed offset is 12, which refers to the 13th byte of the packet. 3. The offset value 0 refers to the first byte of the packet.
23:16	RW	0x00	Filter2_Offset Filter2 Offset This filter offset defines the offset (within the packet) from which the filter examines the packets. 1. This 8-bit pattern-offset is the offset for the filter first byte to be examined. 2. The minimum allowed offset is 12, which refers to the 13th byte of the packet. 3. The offset value 0 refers to the first byte of the packet.

Bit	Attr	Reset Value	Description
15:8	RW	0x00	Filter1_Offset Filter1 Offset This filter offset defines the offset (within the packet) from which the filter examines the packets. 1. This 8-bit pattern-offset is the offset for the filter first byte to be examined. 2. The minimum allowed offset is 12, which refers to the 13th byte of the packet. 3. The offset value 0 refers to the first byte of the packet.
7:0	RW	0x00	Filter0_Offset Filter0 Offset This filter offset defines the offset (within the packet) from which the filter examines the packets. 1. This 8-bit pattern-offset is the offset for the filter first byte to be examined. 2. The minimum allowed offset is 12, which refers to the 13th byte of the packet. 3. The offset value 0 refers to the first byte of the packet.

GMAC_RWK_FILTER_COMMAND

Address: **Operational Base** + offset (0x00C4)

Bit	Attr	Reset Value	Description
31:20	RO	0x000	reserved
19:16	RW	0x0	Filter2_Command Filter2 Command The 4-bit filter command controls the filter operation. 1. Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. 2. Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. 3. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". 4. Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. 5. Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
15:12	RO	0x0	reserved
11:8	RW	0x0	Filter1_Command Filter1 Command The 4-bit filter command controls the filter operation. 1. Bit 3 specifies the address type, defining the destination address type of the pattern. 26	RW	0x0	BTB Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. Values:

Rockchip Confidential

Bit	Attr	Reset Value	Description
			1'b0: Back to Back transactions disabled 1'b1: Back to Back transactions enabled
25:21	RW	0x00	PA Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. For RevMII, this field gives the PHY Address of the RevMII module. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
20:16	RW	0x00	RDA Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. For RevMII, these bits select the CSR register in the RevMII Registers set. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15	RO	0x0	reserved
14:12	RW	0x0	NTC Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11:8	RW	0x0	CR CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 4'b0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 4'b0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 4'b0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 4'b0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 4'b0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 4'b0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 4'b0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 4'b0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 4'b1000: CSR clock/4 4'b1001: CSR clock/6 4'b1010: CSR clock/8 4'b1011: CSR clock/10 4'b1100: CSR clock/12 4'b1101: CSR clock/14 4'b1110: CSR clock/16 4'b1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY

Bit	Attr	Reset Value	Description
			interface.
7:5	RO	0x0	reserved
4	RW	0x0	SKAP Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. Values: 1'b0: Skip Address Packet is disabled 1'b1: Skip Address Packet is enabled
3	RW	0x0	GOC_1 GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: 2'b00: Reserved 2'b01: Write 2'b10: Post Read Increment Address for Clause 45 PHY 2'b11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. Values: 1'b0: GMII Operation Command 1 is disabled 1'b1: GMII Operation Command 1 is enabled
2	RW	0x0	GOC_0 GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. Values: 1'b0: GMII Operation Command 0 is disabled 1'b1: GMII Operation Command 0 is enabled
1	RW	0x0	C45E Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. Values: 1'b0: Clause 45 PHY is disabled 1'b1: Clause 45 PHY is enabled
0	RW	0x0	GB GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDl field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Note: Even if the addressed PHY is not present, there is no

Bit	Attr	Reset Value	Description
8	RW	0x0	UCDBC Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. Values: 1'b0: Update MMC Counters for Dropped Broadcast Packets is disabled 1'b1: Update MMC Counters for Dropped Broadcast Packets is enabled
7:6	RO	0x0	reserved
5	RW	0x0	CNTPRSTLVL Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. Values: 1'b0: Full-Half Preset is disabled 1'b1: Full-Half Preset is enabled
4	RW	0x0	CNTPRST Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Values: 1'b0: Counters Preset is disabled 1'b1: Counters Preset is enabled
3	RW	0x0	CNTFREEZ MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. Values: 1'b0: MMC Counter Freeze is disabled 1'b1: MMC Counter Freeze is enabled

31:0	RO	0x00000000	RXICMPERROCT RxICMP Error Octets This field indicates the number of bytes received in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

GMAC_MAC_TIMESTAMP_CONTROL

Address: **Operational Base** + offset (0x0B00)

Bit	Attr	Reset Value	Description
31:29	RO	0x0	reserved
28	RW	0x0	AV8021ASMEN AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. Values: 1'b0: AV 802.1AS Mode is disabled 1'b1: AV 802.1AS Mode is enabled
27:25	RO	0x0	reserved
24	RW	0x0	TXTSSTSM Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_Tx_Timestamp_Status_Nanoseconds register. Values: 1'b0: Transmit Timestamp Status Mode is disabled 1'b1: Transmit Timestamp Status Mode is enabled
23:19	RO	0x00	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
18	RW	0x0	TSENMACADDR Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. Values: 1'b0: MAC Address for PTP Packet Filtering is disabled 1'b1: MAC Address for PTP Packet Filtering is enabled
17:16	RW	0x0	SNAPTYPSEL Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
15	RW	0x0	TSMSTRENA Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. Values: 1'b0: Snapshot for Messages Relevant to Master is disabled 1'b1: Snapshot for Messages Relevant to Master is enabled
14	RW	0x0	TSEVNTENA Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. Values: 1'b0: Timestamp Snapshot for Event Messages is disabled 1'b1: Timestamp Snapshot for Event Messages is enabled
13	RW	0x0	TSIPV4ENA Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. Values: 1'b0: Processing of PTP Packets Sent over IPv4-UDP is disabled 1'b1: Processing of PTP Packets Sent over IPv4-UDP is enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
12	RW	0x0	TSIPV6ENA Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. Values: 1'b0: Processing of PTP Packets Sent over IPv6-UDP is disabled 1'b1: Processing of PTP Packets Sent over IPv6-UDP is enabled
11	RW	0x0	TSIPENA Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. Values: 1'b0: Processing of PTP over Ethernet Packets is disabled 1'b1: Processing of PTP over Ethernet Packets is enabled
10	RW	0x0	TSVER2ENA Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. Values: 1'b0: PTP Packet Processing for Version 2 Format is disabled 1'b1: PTP Packet Processing for Version 2 Format is enabled
9	RW	0x0	TSCTRLSSR Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. Values: 1'b0: Timestamp Digital or Binary Rollover Control is disabled 1'b1: Timestamp Digital or Binary Rollover Control is enabled
8	RW	0x0	TSENALL Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. Values: 1'b0: Timestamp for All Packets disabled 1'b1: Timestamp for All Packets enabled
7	RO	0x0	reserved
6	RW	0x0	PTGE Presentation Time Generation Enable When this bit is set the Presentation Time generation will be enabled. Values: 0x0 (DISABLE): Presentation Time Generation is disabled 0x1 (ENABLE): Presentation Time Generation is enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
5	RW	0x0	TSADDREG Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Addend Register is not updated 1'b1: Addend Register is updated
4	RO	0x0	reserved
3	RW	0x0	TSUPDT Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated.When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Timestamp is not updated 1'b1: Timestamp is updated
2	RW	0x0	TSINIT Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Timestamp is not initialized 1'b1: Timestamp is initialized
1	RW	0x0	TSCFUPDT Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. Values: 1'b0: Coarse method is used to update system timestamp 1'b1: Fine method is used to update system timestamp

Rockchip Confidential

Bit	Attr	Reset Value	Description
0	RW	0x0	TSENA Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. Values: 1'b0: Timestamp is disabled 1'b1: Timestamp is enabled

GMAC_MAC_SUB_SECOND_INCREMENT

Address: **Operational Base** + offset (0x0B04)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RW	0x00	SSINC Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15:0	RO	0x0000	reserved

GMAC_MAC_SYSTEM_TIME_SECS

Address: **Operational Base** + offset (0x0B08)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	TSS Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

GMAC_MAC_SYSTEM_TIME_NS

Address: **Operational Base** + offset (0x0B0C)

Bit	Attr	Reset Value	Description
31	RO	0x0	reserved
30:0	RW	0x00000000	TSSS Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

GMAC_MAC_SYS_TIME_SECS_UPDATE

Address: **Operational Base** + offset (0x0B10)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	TSS Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, the TSS field in the MAC_Timestamp_Seconds_Update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

GMAC_MAC_SYS_TIME_NS_UPDATE

Address: **Operational Base** + offset (0x0B14)

Bit	Attr	Reset Value	Description
31	RW	0x0	ADDSUB Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. Values: 1'b0: Add time 1'b1: Subtract time
30:0	RW	0x00000000	TSSS Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register.When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_Timestamp_Control is set, the programmed value must be 10^9 - <sub-second value>. When TSCTRLSSR bit in MAC_Timestamp_Control is reset, the programmed value must be 2^31 - <sub-second_value>. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set.

GMAC_MAC_TIMESTAMP_ADDEND

Address: **Operational Base** + offset (0x0B18)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	TSAR Timestamp Addend Register This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

Rockchip Confidential

GMAC_MAC_TIMESTAMP_STATUS

Address: **Operational Base** + offset (0x0B20)

Bit	Attr	Reset Value	Description
31:30	RO	0x0	reserved
29:25	RO	0x00	ATSNS Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. A value equal to the selected depth of FIFO (4, 8, or 16) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.
24	RO	0x0	ATSSTM Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected. Values: 1'b0: Auxiliary Timestamp Snapshot Trigger Missed status not detected 1'b1: Auxiliary Timestamp Snapshot Trigger Missed status detected
23:16	RO	0x00	reserved
15	RO	0x0	TXTSSIS Tx Timestamp Status Interrupt Status In non-EQOS_CORE configurations when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the MAC_Tx_Timestamp_Status_Seconds register is read (or write to MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set). Values: 1'b0: Tx Timestamp Status Interrupt status not detected 1'b1: Tx Timestamp Status Interrupt status detected
14:4	RO	0x000	reserved
3	RO	0x0	TSTRGTERR0 Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: 1'b0: Timestamp Target Time Error status not detected 1'b1: Timestamp Target Time Error status detected

Rockchip Confidential

Bit	Attr	Reset Value	Description
2	RO	0x0	AUXTSTRIG Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: 1'b0: Auxiliary Timestamp Trigger Snapshot status not detected 1'b1: Auxiliary Timestamp Trigger Snapshot status detected
1	RO	0x0	TSTARGT0 Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: 1'b0: Timestamp Target Time Reached status not detected 1'b1: Timestamp Target Time Reached status detected
0	RO	0x0	TSSOVF Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: 1'b0: Timestamp Seconds Overflow status not detected 1'b1: Timestamp Seconds Overflow status detected

GMAC_MAC_TX_TS_STATUS_NS

Address: **Operational Base** + offset (0x0B30)

Bit	Attr	Reset Value	Description
31	RO	0x0	TXTSSMIS Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: 1. The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset. 2. The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event. Values: 1'b0: Transmit Timestamp Status Missed status not detected 1'b1: Transmit Timestamp Status Missed status detected
30:0	RO	0x00000000	TXTSSLO Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

Rockchip Confidential

GMAC_MAC_TX_TS_STATUS_SECS

Address: **Operational Base** + offset (0x0B34)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	TXTSSHI Transmit Timestamp Status High This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

GMAC_MAC_AUXILIARY_CONTROL

Address: **Operational Base** + offset (0x0B40)

Bit	Attr	Reset Value	Description
31:5	RO	0x0000000	reserved
4	RW	0x0	ATSEN0 Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. Values: 0x0 (DISABLE): Auxiliary Snapshot 0 is disabled 0x1 (ENABLE): Auxiliary Snapshot 0 is enabled
3:1	RO	0x0	reserved
0	RW	0x0	ATSFC Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Auxiliary Snapshot FIFO Clear is disabled 1'b1: Auxiliary Snapshot FIFO Clear is enabled

GMAC_MAC_AUXILIARY_TS_NS

Address: **Operational Base** + offset (0x0B48)

Bit	Attr	Reset Value	Description
31	RO	0x0	reserved
30:0	RO	0x00000000	AUXTSLO Auxiliary Timestamp Contains the lower 31 bits (nanoseconds field) of the auxiliary timestamp.

GMAC_MAC_AUXILIARY_TS_SECS

Address: **Operational Base** + offset (0x0B4C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	AUXTSHI Auxiliary Timestamp Contains the lower 32 bits of the Seconds field of the auxiliary timestamp.

GMAC_MAC_TS_INGRESS_CORR_NS

Address: **Operational Base** + offset (0x0B58)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	TSIC Timestamp Ingress Correction This field contains the ingress path correction value as defined by the Ingress Correction expression.

GMAC_MAC_TS_EGRESS_CORR_NS

Address: **Operational Base** + offset (0x0B5C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	TSEC Timestamp Egress Correction This field contains the nanoseconds part of the egress path correction value as defined by the Egress Correction expression.

GMAC_MAC_TS_INGRESS_LATENCY

Address: **Operational Base** + offset (0x0B68)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RO	0x00	ITLNS Ingress Timestamp Latency, in sub-nanoseconds This register holds the average latency in sub-nanoseconds between the input ports (phy_rxd_i) of MAC and the actual point (GMII/MII) where the ingress timestamp is taken.
15:8	RO	0x00	ITLSNS Ingress Timestamp Latency, in nanoseconds This register holds the average latency in nanoseconds between the input ports (phy_rxd_i) of MAC and the actual point (GMII/MII) where the ingress timestamp is taken.
7:0	RO	0x00	reserved

GMAC_MAC_TS_EGRESS_LATENCY

Address: **Operational Base** + offset (0x0B6C)

Bit	Attr	Reset Value	Description
31:24	RO	0x00	reserved
23:16	RO	0x00	ETLNS Egress Timestamp Latency, in nanoseconds This register holds the average latency in nanoseconds between the actual point (GMII/MII) where the egress timestamp is taken and the output ports (phy_txd_o) of the MAC.
15:8	RO	0x00	ETLSNS Egress Timestamp Latency, in sub-nanoseconds This register holds the average latency in sub-nanoseconds between the actual point (GMII/MII) where the egress timestamp is taken and the output ports (phy_txd_o) of the MAC.
7:0	RO	0x00	reserved

GMAC_MAC_PPS_CONTROL

Address: **Operational Base** + offset (0x0B70)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
7	RW	0x0	MCGREN0 MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. Values: 0x0 (PPS): 0th PPS instance is enabled to operate in PPS mode 0x1 (MCGR): 0th PPS instance is enabled to operate in MCGR mode
6:5	RW	0x0	TRGTMODSEL0 Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) mode for PPS0 output signal: Values: 0x0 (ONLY_INT): Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 0x1 (RSVD): Reserved 0x2 (INT_ST): Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 0x3 (ONLY_ST): Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
4	RW	0x0	PPSEN0 Flexible PPS Output Mode Enable When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode). Values: 0x0 (DISABLE): Flexible PPS Output Mode is disabled 0x1 (ENABLE): Flexible PPS Output Mode is enabled
3:0	RW	0x0	PPSCTRL_PPSCMD PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: 4'b0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. 4'b0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. 4'b0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. 4'b0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. ... 4'b1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number.

Rockchip Confidential

Bit	Attr	Reset Value	Description
			The actual clock is of different frequency that gets synchronized every second. For example: 1. When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms. 2. When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high). 3. When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high). This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.

GMAC_MAC_PPS0_TARGET_TIME_SECONDS

Address: **Operational Base** + offset (0x0B80)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	TSTRH0 PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_Control register. If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and PTGE field of MAC_Timestamp_Control Register is set with Presentation time control set in recovery mode, then these bits indicate the TPT being programmed by the application and in generation mode it indicates the CPT generated at the sampled trigger.

GMAC_MAC_PPS0_TARGET_TIME_NS

Address: **Operational Base** + offset (0x0B84)

Bit	Attr	Reset Value	Description
31	RW	0x0	TRGTBUSY0 PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. Values: 0x0 (INACTIVE): PPS Target Time Register Busy status is not detected 0x1 (ACTIVE): PPS Target Time Register Busy is detected

Rockchip Confidential

Bit	Attr	Reset Value	Description
30:0	RW	0x00000000	TTSL0 Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

GMAC_MAC_PPS0_INTERVAL

Address: **Operational Base** + offset (0x0B88)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	PPSINT0 PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

GMAC_MAC_PPS0_WIDTH

Address: **Operational Base** + offset (0x0B8C)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	PPSWIDTH0 PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

GMAC_MTL_OPERATION_MODE

Address: **Operational Base** + offset (0x0C00)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
9	RW	0x0	CNTCLR Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNT_PRESET bit, CNT_PRESET has precedence. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 0x0 (DISABLE): Counters are not reset 0x1 (ENABLE): All counters are reset
8	RW	0x0	CNTPRST Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNT_PRESET bit, CNT_PRESET has precedence. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 0x0 (DISABLE): Counters are not reset 0x1 (ENABLE): All counters are reset
7:2	RO	0x00	reserved
1	RW	0x0	DTXSTS Drop Transmit Status When this bit is set, the Tx packet status received from the MAC is dropped in the MTL. When this bit is reset, the Tx packet status received from the MAC is forwarded to the application. Values: 0x0 (DISABLE): Drop Transmit Status is disabled 0x1 (ENABLE): Drop Transmit Status is enabled
0	RO	0x0	reserved

GMAC_MTL_DBG_CTL

Address: **Operational Base** + offset (0x0C08)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15	RW	0x0	STSIE Transmit Status Available Interrupt Status Enable When this bit is set, an interrupt is generated when Transmit status is available in slave mode. Values: 1'b0: Transmit Packet Available Interrupt Status is disabled 1'b1: Transmit Packet Available Interrupt Status is enabled
14	RW	0x0	PKTIE Receive Packet Available Interrupt Status Enable When this bit is set, an interrupt is generated when EOP of received packet is written to the Rx FIFO. Values: 1'b0: Receive Packet Available Interrupt Status is disabled 1'b1: Receive Packet Available Interrupt Status is enabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
13:12	RW	0x0	FIFOSEL FIFO Selected for Access This field indicates the FIFO selected for debug access: Values: 2'b00: Tx FIFO 2'b01: Tx Status FIFO (only read access when SLVMOD is set) 2'b10: TSO FIFO (cannot be accessed when SLVMOD is set) 2'b11: Rx FIFO
11	RW	0x0	FIFOWREN FIFO Write Enable When this bit is set, it enables the Write operation on selected FIFO when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Values: 1'b0: FIFO Write is disabled 1'b1: FIFO Write is enabled
10	RW	0x0	FIFORDEN FIFO Read Enable When this bit is set, it enables the Read operation on selected FIFO when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Values: 1'b0: FIFO Read is disabled 1'b1: FIFO Read is enabled
9	RW	0x0	RSTSEL Reset Pointers of Selected FIFO When this bit is set, the pointers of the currently-selected FIFO are reset when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Values: 1'b0: Reset Pointers of Selected FIFO is disabled 1'b1: Reset Pointers of Selected FIFO is enabled
8	RW	0x0	RSTALL Reset All Pointers When this bit is set, the pointers of all FIFOs are reset when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Values: 1'b0: Reset All Pointers is disabled 1'b1: Reset All Pointers is enabled
7	RO	0x0	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
6:5	RW	0x0	PKTSTATE Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Tx FIFO: 2'b00: Packet Data 2'b01: Control Word 2'b10: SOP Data 2'b11: EOP Data Rx FIFO: 2'b00: Packet Data 2'b01: Normal Status 2'b10: Last Status 2'b11: EOP Values: 2'b00: Packet Data 2'b01: Control Word/Normal Status 2'b10: SOP Data/Last Status 2'b11: EOP Data/EOP
4	RO	0x0	reserved
3:2	RW	0x0	BYTEEN Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. Values: 2'b00: Byte 0 valid 2'b01: Byte 0 and Byte 1 are valid 2'b10: Byte 0, Byte 1, and Byte 2 are valid 2'b11: All four bytes are valid
1	RW	0x0	DBGMOD Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. In this mode, the following access types are allowed: 1. Read and Write access to Tx FIFO, TSO FIFO, and Rx FIFO 2. Read access is allowed to Tx Status FIFO. When this bit is reset, it indicates that the current access to the FIFO is slave access bypassing the DMA. In this mode, the following access are allowed: 1. Write access to the Tx FIFO 2. Read access to the Rx FIFO and Tx Status FIFO Values: 1'b0: Debug Mode Access to FIFO is disabled 1'b1: Debug Mode Access to FIFO is enabled
0	RW	0x0	FDBGEN FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. When this bit is reset, it indicates that the FIFO can be accessed only through a master interface. Values: 1'b0: FIFO Debug Access is disabled 1'b1: FIFO Debug Access is enabled

GMAC_MTL_DBG_STS

Address: **Operational Base** + offset (0x0C0C)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:15	RO	0x00200	LOCR Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively. Reset: In single Tx Queue configurations, (DWC_EQOS_TXFIFO_SIZE/(DWC_EQOS_DATAWIDTH/8)), Otherwise 0000H.
14:10	RO	0x00	reserved
9	RW	0x0	STSI Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit. Values: 1'b0: Transmit Status Available Interrupt Status not detected 1'b1: Transmit Status Available Interrupt Status detected
8	RW	0x0	PKTI Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit. Values: 1'b0: Receive Packet Available Interrupt Status not detected 1'b1: Receive Packet Available Interrupt Status detected
7:5	RO	0x0	reserved
4:3	RO	0x0	BYTEEN Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. Values: 2'b00: Byte 0 valid 2'b01: Byte 0 and Byte 1 are valid 2'b10: Byte 0, Byte 1, and Byte 2 are valid 2'b11: All four bytes are valid
2:1	RO	0x0	PKTSTATE Encoded Packet State This field is used to get the control or status information of the selected FIFO. Bit	Attr	Reset Value	Description
			2'b01: Control Word/Normal Status 2'b10: SOP Data/Last Status 2'b11: EOP Data/EOP
0	RO	0x0	FIFOBUSY FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: 1. All other fields of this register 2. All fields of the MTL_FIFO_Debug_Data register Values: 1'b0: FIFO Busy not detected 1'b1: FIFO Busy detected

GMAC_MTL_FIFO_DEBUG_DATA

Address: **Operational Base** + offset (0x0C10)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	FDBGDATA FIFO Debug Data During debug or slave access write operation, this field contains the data to be written to the Tx FIFO, Rx FIFO, or TSO FIFO. During debug or slave access read operation, this field contains the data read from the Tx FIFO, Rx FIFO, TSO FIFO, or Tx Status FIFO.

GMAC_MTL_INTERRUPT_STATUS

Address: **Operational Base** + offset (0x0C20)

Bit	Attr	Reset Value	Description
31:18	RO	0x0000	reserved
17	RO	0x0	DBGIS Debug Interrupt status This bit indicates an interrupt event during the slave access. To reset this bit, the application must read the FIFO Debug Access Status register to get the exact cause of the interrupt and clear its source. Values: 1'b0: Debug Interrupt status not detected 1'b1: Debug Interrupt status detected
16:1	RO	0x0000	reserved
0	RO	0x0	Q0IS Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. To reset this bit, the application must read Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source. Values: 1'b0: Queue 0 Interrupt status not detected 1'b1: Queue 0 Interrupt status detected

GMAC_MTL_TXQ0_OPERATION_MODE

Address: **Operational Base** + offset (0x0D00)

Bit	Attr	Reset Value	Description
31:7	RO	0x0000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
6:4	RW	0x0	TTC Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. Values: 3'b000: 32 bytes 3'b001: 64 bytes 3'b010: 96 bytes 3'b011: 128 bytes 3'b100: 192 bytes 3'b101: 256 bytes 3'b110: 384 bytes 3'b111: 512 bytes
3:2	RO	0x0	reserved
1	RW	0x0	TSF Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. Values: 1'b0: Transmit Store and Forward is disabled 1'b1: Transmit Store and Forward is enabled
0	RW	0x0	FTQ Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Values: 1'b0: Flush Transmit Queue is disabled 1'b1: Flush Transmit Queue is enabled

GMAC_MTL_TXQ0_UNDERFLOW

Rockchip Confidential

Bit	Attr	Reset Value	Description
11	RO	0x0	UFCNTOVF Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. Values: 1'b0: Overflow not detected for Underflow Packet Counter 1'b1: Overflow detected for Underflow Packet Counter
10:0	RO	0x000	UFFRMCNT Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

GMAC_MTL_TXQ0_DEBUG

Address: **Operational Base** + offset (0x0D08)

Bit	Attr	Reset Value	Description
31:23	RO	0x000	reserved
22:20	RO	0x0	STXSTSF Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19	RO	0x0	reserved
18:16	RO	0x0	PTXQ Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15:6	RO	0x000	reserved
5	RO	0x0	TXSTSFSTS MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. Values: 1'b0: MTL Tx Status FIFO Full status is not detected 1'b1: MTL Tx Status FIFO Full status is detected
4	RO	0x0	TXQSTS MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. Values: 1'b0: MTL Tx Queue Not Empty status is not detected 1'b1: MTL Tx Queue Not Empty status is detected

Rockchip Confidential

Bit	Attr	Reset Value	Description
3	RO	0x0	TWCSTS MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. Values: 1'b0: MTL Tx Queue Write Controller status is not detected 1'b1: MTL Tx Queue Write Controller status is detected
2:1	RO	0x0	TRCSTS MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: Values: 2'b00: Idle state 2'b01: Read state (transferring data to the MAC transmitter) 2'b10: Waiting for pending Tx Status from the MAC transmitter 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
0	RO	0x0	TXQPAUSED Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: 1. Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled 2. Reception of 802.3x Pause packet when PFC is disabled Values: 1'b0: Transmit Queue in Pause status is not detected 1'b1: Transmit Queue in Pause status is detected

GMAC_MTL_Q0_INTERRUPT_CTRL_STATUS

Address: **Operational Base** + offset (0x0D2C)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved
24	RW	0x0	RXOIE Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. Values: 1'b0: Receive Queue Overflow Interrupt is disabled 1'b1: Receive Queue Overflow Interrupt is enabled
23:17	RO	0x00	reserved
16	RW	0x0	RXOVFIS Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Values: 1'b0: Receive Queue Overflow Interrupt Status not detected 1'b1: Receive Queue Overflow Interrupt Status detected
15:9	RO	0x00	reserved

Rockchip Confidential

8	RW	0x0	TXUIE Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. Values: 1'b0: Transmit Queue Underflow Interrupt Status is disabled 1'b1: Transmit Queue Underflow Interrupt Status is enabled
7:1	RO	0x00	reserved
0	RW	0x0	TXUNFIS Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Values: 1'b0: Transmit Queue Underflow Interrupt Status not detected 1'b1: Transmit Queue Underflow Interrupt Status detected

GMAC_MTL_RXQ0_OPERATION_MODE

Address: **Operational Base** + offset (0x0D30)

Bit	Attr	Reset Value	Description
31:18	RO	0x0000	reserved
17:14	RW	0x0	RFD Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0: Full minus 1 KB, that is, FULL 1 KB 1: Full minus 1.5 KB, that is, FULL 1.5 KB 2: Full minus 2 KB, that is, FULL 2 KB 3: Full minus 2.5 KB, that is, FULL 2.5 KB ... 62: Full minus 32 KB, that is, FULL 32 KB 63: Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13:12	RO	0x0	reserved
11:8	RW	0x0	RFA Threshold for Activating Flow Control (in half-duplex and full-duplex) These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.

Rockchip Confidential

Bit	Attr	Reset Value	Description
7	RW	0x0	EHFC Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. Values: 1'b0: Hardware Flow Control is disabled 1'b1: Hardware Flow Control is enabled
6	RW	0x0	DIS_TCP_EF Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. Values: 1'b0: Dropping of TCP/IP Checksum Error Packets is enabled 1'b1: Dropping of TCP/IP Checksum Error Packets is disabled
5	RW	0x0	RSF Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. Values: 1'b0: Receive Queue Store and Forward is disabled 1'b1: Receive Queue Store and Forward is enabled
4	RW	0x0	FEP Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. Values: 1'b0: Forward Error Packets is disabled 1'b1: Forward Error Packets is enabled
3	RW	0x0	FUP Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. Values: 1'b0: Forward Undersized Good Packets is disabled

Rockchip Confidential

Bit	Attr	Reset Value	Description
			1'b1: Forward Undersized Good Packets is enabled
2	RO	0x0	reserved
1:0	RW	0x0	RTC Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

GMAC_MTL_RXQ0_MISS_PKT_OVF_CNT

Address: **Operational Base** + offset (0x0D34)

Bit	Attr	Reset Value	Description
31:28	RO	0x0	reserved
27	RO	0x0	MISCNTOVF Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. Values: 1'b0: Missed Packet Counter overflow not detected 1'b1: Missed Packet Counter overflow detected
26:16	RO	0x000	MISPKTCNT Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. In EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations, This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15:12	RO	0x0	reserved
11	RO	0x0	OVFCNTOVF Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. Values: 1'b0: Overflow Counter overflow not detected 1'b1: Overflow Counter overflow detected
10:0	RO	0x000	OVFPKTCNT Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

31:4	RO	0x0000000	reserved
3:0	RW	0x0	LPIEI LPI Entry Interval Contains the number of system clock cycles, multiplied by 64, to wait for an activity in the DWC_ether_qos to enter into the AXI low power state. 0 indicates 64 clock cycles.

GMAC_DMA_CH0_CONTROL

Address: **Operational Base** + offset (0x1100)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
24	RW	0x0	SPH Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload. This bit is available only if Enable Split Header Structure option is selected. Values: 0x0 (DISABLE): Split Headers feature is disabled 0x1 (ENABLE): Split Headers feature is enabled
23:21	RO	0x0	reserved
20:18	RW	0x0	DSL Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17	RO	0x0	reserved
16	RW	0x0	PBLx8 8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH0_Tx_Control and Bits[21:16] in DMA_CH0_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0x0 (DISABLE): 8xPBL mode is disabled 0x1 (ENABLE): 8xPBL mode is enabled
15:14	RO	0x0	reserved
13:0	RW	0x0000	MSS Maximum Segment Size This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of DMA_CH0_Tx_Control register is set. The value programmed in this field must be more than the configured Datawidth in bytes. It is recommended to use a MSS value of 64 bytes or more.

GMAC_DMA_CH0_TX_CONTROL

Address: **Operational Base** + offset (0x1104)

Bit	Attr	Reset Value	Description
31:22	RO	0x000	reserved
21:16	RW	0x00	TxPBL Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps:

Rockchip Confidential

Bit	Attr	Reset Value	Description
			1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	RW	0x0	IPBL Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0x0 (DISABLE): Ignore PBL Requirement is disabled 0x1 (ENABLE): Ignore PBL Requirement is enabled
14:13	RW	0x0	TSE_MODE TSE Mode 00: TSO/USO (segmentation functionality is enabled). In this mode, the setting of TSE bit enables the TSO/USO segmentation. 01: UFO with Checksum (UDP Fragmentation over IPv4 with Checksum). In this mode, the setting of TSE bit enables the UDP fragmentation functionality with Checksum for all the UDP packets. 10: UFO without Checksum (UDP Fragmentation over IPv4 with Checksum). In this mode, the setting of TSE bit enables the UDP fragmentation functionality without Checksum for all the UDP packets. 11: Reserved 0x0 (TSO_USO): TSO/USO 0x1 (UFOWC): UFO with Checksum 0x2 (UFOWOC): UFO without Checksum 0x3 (RSVD): Reserved
12	RW	0x0	TSE TCP Segmentation Enabled When this bit is set, the DMA performs the TCP segmentation or UDP Segmentation/Fragmentation for packets in this channel. The TCP segmentation or UDP packet's segmentation/Fragmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor.When this bit is set, the TxPBL value must be greater than 4. 0x0 (DISABLE): TCP Segmentation is disabled 0x1 (ENABLE): TCP Segmentation is enabled

Bit	Attr	Reset Value	Description
4	RW	0x0	OSF Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0x0 (DISABLE): Operate on Second Packet disabled 0x1 (ENABLE): Operate on Second Packet enabled
3:1	RO	0x0	reserved
0	RW	0x0	ST Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: 1.The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. 2.The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0x0 (STOP): Stop Transmission Command 0x1 (START): Start Transmission Command

GMAC_DMA_CH0_RX_CONTROL

Address: **Operational Base** + offset (0x1108)

Bit	Attr	Reset Value	Description
31	RW	0x0	RPF Rx Packet Flush When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the

Rockchip Confidential

Bit	Attr	Reset Value	Description
			corresponding RxQueue. 0x0 (DISABLE): Rx Packet Flush is disabled 0x1 (ENABLE): Rx Packet Flush is enabled
30:22	RO	0x000	reserved
21:16	RW	0x00	RxPBL Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	RO	0x0	reserved
14:4	RW	0x000	RBSZ_13_y Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_3_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_3_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3:1	RO	0x0	RBSZ_3_0 Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_3_0. The RBSZ_3_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO)

Bit	Attr	Reset Value	Description
10:0	RO	0x000	MFC Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in DMA_CH0_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

GMAC_DMA_CH0_RX_ERI_CNT

Address: **Operational Base** + offset (0x1168)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RO	0x0	ECNT ERI Counter When ERIC bit of DMA_CH0_RX_Control register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter will get reset at the start of new packet.

38.5 Interface Description

There are two MAC Controllers in RK3506, and each has one set of IO interface, but some pins are also connected with Rockchip Matrix IO, as shown below tables. In addition, the schmitt trigger of mac0_rxd0/1 and mac1_rxd0/1 IO must be disabled.

Table 38-3 MAC Interface

38.6 Application Note

38.6.1 Descriptors

The DMA engine uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The MAC supports the following two types of descriptors:

Rockchip Confidential

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted

The MAC supports the ring structure for the DMA descriptor.

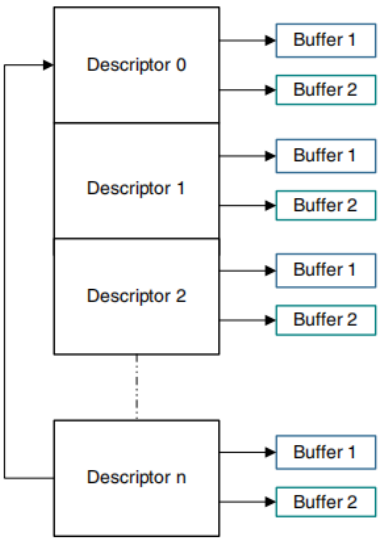

Fig. 38-10 Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process.

The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer

The DMA automatically wraps around the base address when the end of ring is reached. For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

38.6.2 Transmit Descriptors

The DMA in MAC requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format.

38.6.3 Transmit Normal Descriptor (Read Format)

Table 38-5 TDES0 Normal Descriptor (Read Format)

Rockchip Confidential

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: ■ TSE bit of TDES3 ■ FD bit of TDES3

Table 38-6 TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

Table 38-7 TDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: ■ 2'b00: Do not add a VLAN tag. ■ 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. ■ 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. ■ 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the

Rockchip Confidential

Bit	Name	Description
		core
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

Table 38-8 TDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: ■ 2'b00: CRC and Pad Insertion. The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. ■ 2'b01: CRC Insertion (Disable Pad Insertion). The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. ■ 2'b10: Disable CRC Insertion. The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.

Rockchip Confidential

Bit	Name	Description
		■ 2'b11: CRC Replacement. The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: ■ 2'b00: Do not include the source address ■ 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. ■ 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. ■ 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TCP Segmentation Enable When this bit is set, the DMA performs the TCP/UDP segmentation or UDP fragmentation for a packet depending on the TSE_MODE[1:0] bit of the DMA_CH(#i)_Tx_Control Register. This bit is valid only if the FD bit is set.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length

Rockchip Confidential

Bit	Name	Description
		These bits control the checksum calculation and insertion. The following list describes the bit encoding: ■ 2'b00: Checksum Insertion Disabled. ■ 2'b01: Only IP header checksum calculation and insertion are enabled. ■ 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. ■ 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

38.6.4 Transmit Normal Descriptor (Write-back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits. The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet. This format is only applicable to the last descriptor of a packet.

Table 38-9 TDES0 Normal Descriptor (Write-Back Format)

Rockchip Confidential

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set

Table 38-10 TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

Table 38-11 TDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	Reserved	Reserved

Table 38-12 TDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:24	Reserved	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: ■ Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet ■ All 1s ■ CTXT, LD, and FD bits set to 1 Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1.

Rockchip Confidential

Bit	Name	Description
		When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register. Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	Reserved	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by MAC.
15	ES	Error Summary This bit indicates the logical OR of the following bits: ■ TDES3[0]: IP Header Error ■ TDES3[14]: Jabber Timeout ■ TDES3[13]: Packet Flush ■ TDES3[12]: Payload Checksum Error ■ TDES3[11]: Loss of Carrier ■ TDES3[10]: No Carrier ■ TDES3[9]: Late Collision ■ TDES3[8]: Excessive Collision ■ TDES3[3]: Excessive Deferral ■ TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set
14	JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	PF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to

Rockchip Confidential

Bit	Name	Description
		avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: ■ The DMA encountered an empty Transmit Buffer while transmitting the packet ■ The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enter the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit

Rockchip Confidential

Bit	Name	Description
		This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

38.6.5 Programming Guide

38.6.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_Mode, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SysBus_Mode register:

a. AAL

b. Fixed burst or undefined burst

c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.

d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])

4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see section "Descriptors".
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= MAC_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= MAC_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= MAC_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= MAC_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= MAC_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= MAC_NUM_DMA_RX_CH-1)).
7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= MAC_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= MAC_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= MAC_NUM_DMA_RX_CH-1)
8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= MAC_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= MAC_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= MAC_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

Rockchip Confidential

38.6.5.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.
Complete the following steps to initialize the MTL registers:
1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
c. Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
d. Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

38.6.5.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.
The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.
1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
a. Receive All
b. Promiscuous mode
c. Hash or Perfect Filter
d. Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
a. Pause time and other Pause frame control bits
b. Transmit Flow control bits
c. Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_Configuration registers to start the MAC transmitter and receiver.

38.6.5.4 Performing Normal Receive and Transmit Operation

During normal operation of the MAC, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.
For normal operation, complete the following steps:

Rockchip Confidential

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Current_App_RxBuffer)

38.6.5.5 Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time.
1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= MAC_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Configuration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TxQ0_Debug Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug Register and RXQSTS is 0 in MTL_RxQ0_Debug Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

38.6.5.6 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_Timestamp_Control Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during MAC initialization:
1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_Interrupt_Enable Register.
2. Set Bit 0 of MAC_Timestamp_Control Register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_Timestamp_Control Register.
5. Poll the MAC_Timestamp_Control Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_Timestamp_Control Register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value.
8. Set Bit 2 in MAC_Timestamp_Control Register.
The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is enabled
a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
b. Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

Rockchip Confidential

38.6.5.7 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method), complete the following steps:
1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update).
2. Set Bit 3 (TSUPDT) of MAC_Timestamp_Control Register. The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

38.6.5.8 Programming Guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet. Complete the following steps to program TSO:
1. Program the TSE bit of corresponding DMA_CH[n]_Tx_Control register to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
a. Enable TSE in Bit 18 of TDES3
b. Program the length of the un-segmented TCP/IP packet payload in bits [17:0] of TDES3 and the TCP header in bits [22:19] of TDES3.
c. Program the maximum size of the segment in MSS of DMA_CH[n]_Control register or MSS in the context descriptor. If MSS field is programmed in both DMA_CH[n]_Control register and in the context descriptor, the latest software programmed sequence is considered.
3. The header of the unsegmented TCP/IP packet should be in Buffer 1 of the first descriptor and this buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

38.6.5.9 Programming Guidelines for Multi-Channel Multi-Queuing

Transmit

1. Program the Transmit queue size in the TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in the TQS field, the size of the queue is determined.
In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.
2. For a queue to be used, the queue needs to be enabled in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode Register. In DMA configurations, the ST bit of DMA_CH[n]_Tx_Control Register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_Operation_Mode register.
4. Program the MTL_TxQ[n]_Quantum_Weight for DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit and MTL_TxQ[n]_LoCredit registers also need to be programmed as required.
5. If DCB is enabled and PFC function is required, program MAC_TxQ_Prty_Map0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

Receive

1. Program the Receive queue size in the RQS field of MTL_RxQ[n]_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_Rx_Control Register and corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.

Rockchip Confidential

3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register.
   b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 Register.
   c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program
   DCBCPQ in MAC_RxQ_Ctrl1 Register to indicate to MAC which queue should get the DCB packets.
   d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 7.
   e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.
4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a. Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b. Program the MTL_RxQ[n]_Control to decide the weights and the packet arbitration for each RxQ.
   c. If static mapping is programmed in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d. Set RXQ[n]DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of
   packets in each RxQueue.
   e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

38.6.6 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature. The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

Table 38-13 TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 38-14 TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Rockchip Confidential

Table 38-15 TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
15:14	Reserved	Reserved
13:0	MSS	Maximum Segment Size When the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected, the driver can provide maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

Table 38-16 TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the MAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
29:28	Reserved	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Reserved	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: ■ Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet ■ All 1s ■ CD, LD, and FD bits set to 1 Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status Register.

Rockchip Confidential

Bit	Name	Description
		Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:20	Reserved	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: ■ 2'b00: Do not add the inner VLAN tag. ■ 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. ■ 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. ■ 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

38.6.7 Receive Descriptors

The DMA in MAC attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the “Receive Normal Descriptor (Write-Back Format)”. For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded

Rockchip Confidential

in that descriptor). The format and content of the descriptor write back is described in "Receive Context Descriptor".

38.6.8 Receive Normal Descriptors (Read Format)

Table 38-17 TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

Table 38-18 TDES1 Normal Descriptor(Read Format)

Bit	Name	Description
31:0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

Table 38-19 TDES2 Normal Descriptor(Read Format)

Bit	Name	Description
31:0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

Table 38-20 TDES3 Normal Descriptor(Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the MAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ■ The DMA completes the packet reception ■ The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	Reserved	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid.

Rockchip Confidential

Bit	Name	Description
		The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23:0	Reserved	Reserved

38.6.9 Receive Normal Descriptors (Write-Back Format)

Table 38-21 TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

Table 38-22 TDES1 Normal Descriptor(Write-Back Format)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If Bits[18:16] of RDES3 are set to 3'b110, this field contains the MAC Control packet opcode field.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Rockchip Confidential

Bit	Name	Description
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: ■ 0000: No PTP message received ■ 0001: SYNC (all clock types) ■ 0010: Follow_Up (all clock types) ■ 0011: Delay_Req (all clock types) ■ 0100: Delay_Resp (all clock types) ■ 0101: Pdelay_Req (in peer-to-peer transparent clock) ■ 0110: Pdelay_Resp (in peer-to-peer transparent clock) ■ 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) ■ 1000: Announce ■ 1001: Management ■ 1010: Signaling ■ 1011–1110: Reserved ■ 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: ■ The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. ■ The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. ■ The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: ■ The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes.

Rockchip Confidential

Bit	Name	Description
		■ The IP datagram version is not consistent with the Ethernet Type value. ■ Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2:0	PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): ■ 3'b000: Unknown type or IP/AV payload not processed ■ 3'b001: UDP ■ 3'b010: TCP ■ 3'b011: ICMP ■ 3'b110: AV Tagged Data Packet ■ 3'b111: AV Tagged Control Packet ■ 3'b101: AV Untagged Control Packet ■ 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.

Table 38-23 TDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: ■ 000: Filter 0 ■ 001: Filter 1 ■ 010: Filter 2 ■ 011: Filter 3 ■ 100: Filter 4 ■ 101: Filter 5 ■ 110: Filter 6 ■ 111: Filter 7 This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: ■ Layer 3 fields are not enabled and all enabled Layer 4 fields match ■ All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
27	L3FM	Layer 3 Filter Match

Rockchip Confidential

Bit	Name	Description
		When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: ■ All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed ■ All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	VLAN Filter Status When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter. This bit is valid only when MAC_ERVFE is not enabled. If MAC_ERVFE is enabled, the bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only when MAC_ERVFE is enabled. This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled.

Rockchip Confidential

Bit	Name	Description
		For more information, see the Filter Status topic.
13:11	Reserved	Reserved
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

Table 38-24 TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the MAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ■ The DMA completes the packet reception ■ The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} ■ 2’b00: Intermediate Descriptor ■ 2’b01: First Descriptor ■ 2’b10: Reserved ■ 2’b11: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second

Rockchip Confidential

Bit	Name	Description
		buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error

Rockchip Confidential

Bit	Name	Description
		When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: ■ 3'b000: The packet is a length packet ■ 3'b001: The packet is a type packet. ■ 3'b011: The packet is a ARP Request packet type ■ 3'b100: The packet is a type packet with VLAN Tag ■ 3'b101: The packet is a type packet with Double VLAN Tag ■ 3'b110: The packet is a MAC Control packet type ■ 3'b111: The packet is a OAM packet type ■ 3'b010: Reserved
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: ■ RDES3[24]: CRC Error ■ RDES3[19]: Dribble Error ■ RDES3[20]: Receive Error ■ RDES3[22]: Watchdog Timeout ■ RDES3[21]: Overflow Error ■ RDES3[23]: Giant Packet ■ RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled ■ RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled This field is valid only when the LD bit of RDES3 is set.
14	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

38.6.10 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

Table 38-25 TDES0 Context Descriptor

Bit	Name	Description
31:0	RSTL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding

Rockchip Confidential

Bit	Name	Description
		Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

Table 38-26 TDES1 Context Descriptor

Bit	Name	Description
31:0	RSTH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

Table 38-27 TDES2 Context Descriptor

Bit	Name	Description
31:0	Reserved	Reserved

Table 38-28 TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: ■ The DMA completes the packet reception ■ The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor. DMA writes 2’b11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE} ■ 2’b00: Reserved ■ 2’b01: Reserved ■ 2’b10: Context Descriptor ■ 2’b11: Descriptor Error Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using theDE bit along with CTXT bit.
28:0	Reserved	Reserved

38.6.11 Clock Architecture

In RMII mode, reference clock and TX/RX clock be from PHY as following figure. The mux of selecting rmii_speed is GRF_SOC_CON8[3]/GRF_SOC_CON11[3].

Chapter 39 Mobile Storage Host Controller (SDMMC&EMMC)

39.1 Overview

The Mobile Storage Host Controller is designed to support Secure Digital memory (SD-max version 3.01) with 1 bits or 4 bits data width, Multimedia Card (MMC-max version 4.51) with 1 bits or 4 bits data width.
The Host Controller is instantiated for SDMMC, EMMC. The interface difference between these instances is shown in "Interface Description".
The Host Controller supports following features:

- Bus Interface Features:
  - Support AMBA AHB interface for master and slave
  - Supports internal DMA interface(IDMAC)
    - Supports 16/32-bit data transfers
    - Single engine used for transmit and receive, which are mutually exclusive
    - Dual-buffer and chained descriptor linked list
    - Each descriptor can transfer up to 4KB of data in chained mode and 8KB of data in dual-buffer mode
    - Programmable burst size for optimal host bus utilization
  - Support combined single FIFO for both transmit and receive operations
  - Support FIFO size of 256x32
  - Support FIFO over-run and under-run prevention by stopping card clock
- Card Interface Features:
  - Support secure digital memory protocol commands
  - Support secure digital I/O protocol commands
  - Support Multimedia Card protocol commands
  - Support command completion signal and interrupts to host
  - Support CRC generation and error detection
  - Support programmable baud rate
  - Support power management and power switch
  - Support write protection
  - Support hardware reset
  - Support SDIO interrupts in 1-bit and 4-bit modes
  - Support 4-bit mode in SDIO3.0
  - Support SDIO suspend and resume operation
  - Support SDIO read wait
  - Support block size of 1 to 65,535 bytes
  - Support 1-bit and 4-bit SDR modes
  - Supports 4-bit DDR
  - Support boot in 1-bit and 4-bit SDR modes
- Clock Interface Features:
  - Support 0/90/180/270-degree phase shift operation for sample clock (cclk_in_sample) and drive clock(cclk_in_drv) relative to function clock(cclk_in) respectively
  - Support phase tuning using delay line for sample clock(cclk_in_sample) and drive clock(cclk_in_drv) relative to function clock (cclk_in) respectively.
  - The max number of delay element is 128. The average delay for every delay element is 29ps~61ps, the total delay is 3.7ns~7.8ns, varies with VT.

39.2 Block Diagram

The controller consists of the following main functional blocks.

Rockchip Confidential

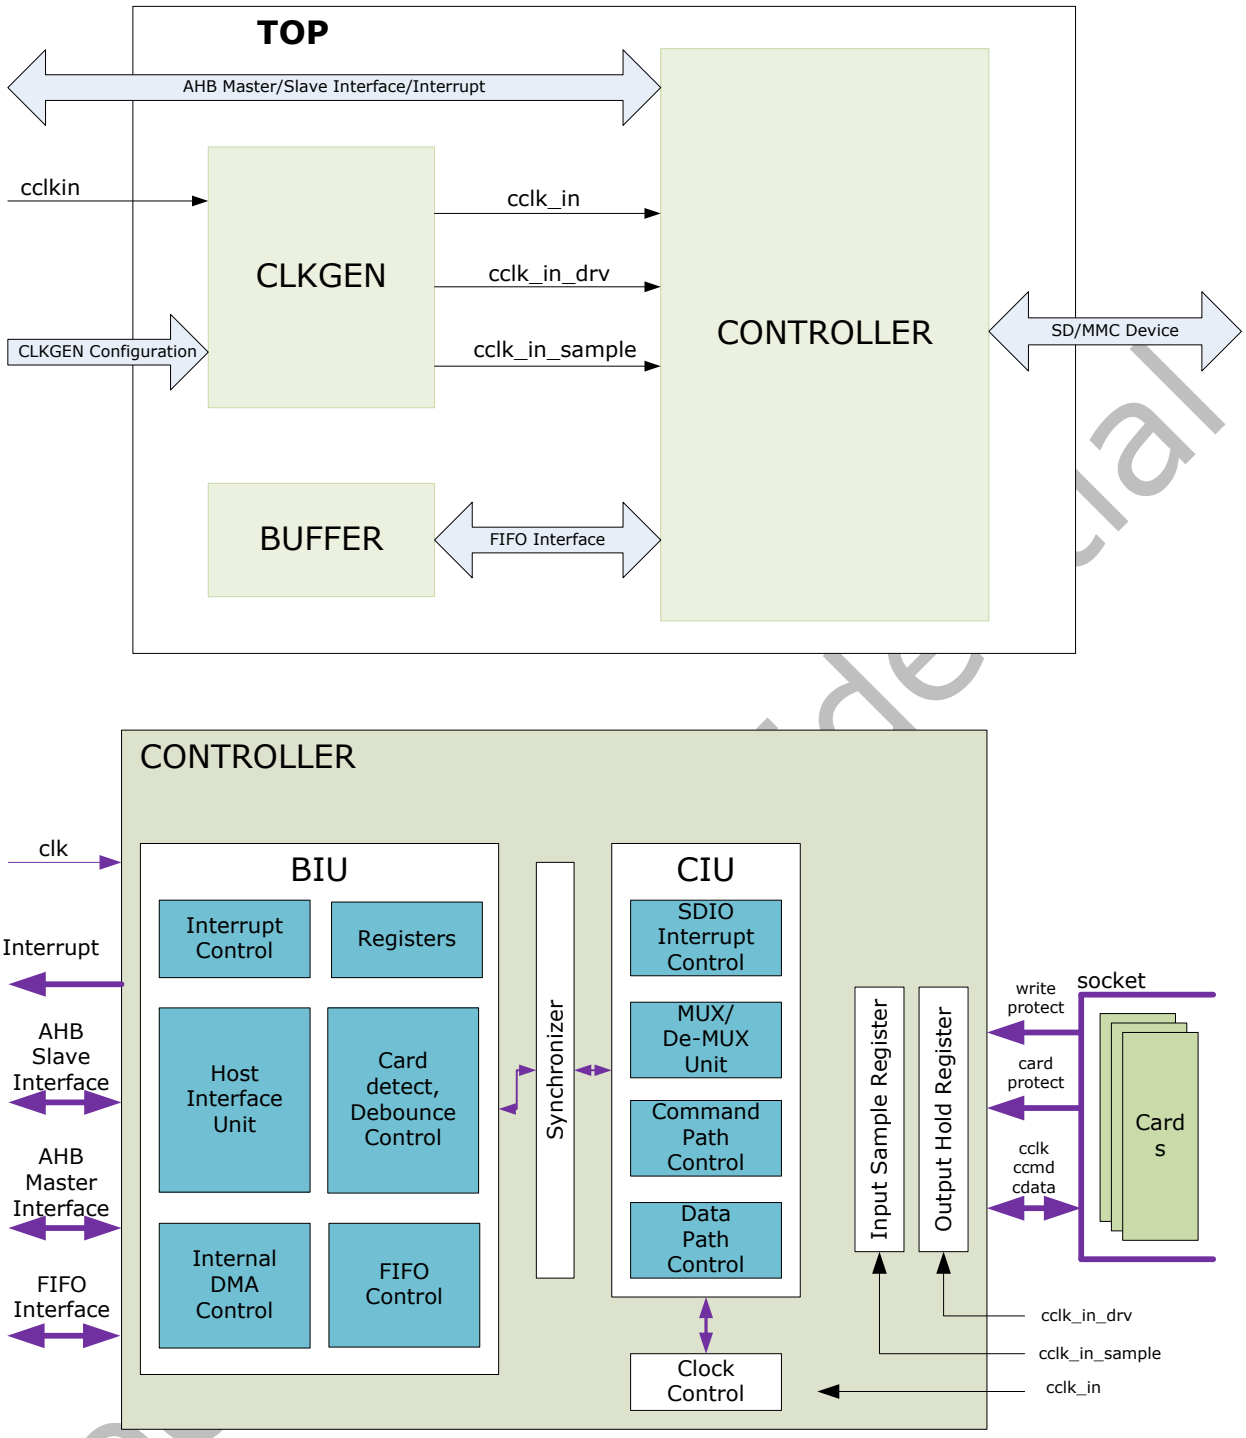

Fig.39-1 Mobile Storage Host Control Block Diagram

- Clock Generate Unit (CLKGEN): Generates card interface clock cclk_in/ cclk_sample/cclk_drv based on cclkin and configuration information.
  - cclkin: original clock
  - cclk_in: functional clock
  - cclk_sample: sample clock
  - cclk_drv: driver clock
- Asynchronous dual-port memory (BUFFER): Use a two-clock synchronous read and synchronous write dual-port RAM. One of the ports is connected to the host clock, and the other port is connected to the card clock.
- Bus Interface Unit (BIU): Provides AMBA AHB interfaces for register and data read/write.
- Card Interface Unit (CIU): Takes care of the SD/MMC protocols and provides clock management.

Rockchip Confidential

39.3 Function Description

39.3.1 Bus Interface Unit

The Bus Interface Unit provides the following functions:

- Host interface
- Interrupt control
- Register access
- External FIFO access

39.3.1.1 Host Interface Unit

The Host Interface Unit is an AHB slave interface, which provides the interface between the SD/MMC card and the host bus.

39.3.1.2 Register Unit

The register unit is part of the bus interface unit; it provides read and write access to the registers.

All registers reside in the Bus Interface Unit clock domain. When a command is sent to a card by setting the start_bit, which is bit[31] of the SDMMC_CMD register, all relevant registers needed for the CIU operation are transferred to the CIU block. During this time, the registers that are transferred from the BIU to the CIU should not be written. The software should wait for the hardware to clear the start bit before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers. The lock is necessary in order to avoid metastability violations, both because the host and card clock domains are different and to prevent illegal software operations.

Once a command start is issued by setting the start_bit of the SDMMC_CMD register, the following registers cannot be reprogrammed until the command is accepted by the card interface unit:

- SDMMC_CMD
- SDMMC_CMDARG
- SDMMC_BYTCNT
- SDMMC_BLKSIZ
- SDMMC_CLKDIV
- SDMMC_CLKENA
- SDMMC_CLKSRC
- SDMMC_TMOUT
- SDMMC_CTYPE

The hardware resets the start_bit once the CIU accepts the command. If a host write to any of these registers is attempted during this locked time, then the write is ignored and the hardware lock error bit is set in the raw interrupt status register. Additionally, if the interrupt is enabled and not masked for a hardware lock error, then an interrupt is sent to the host.

When the Card Interface Unit is in an idle state, it typically takes the following number of clocks for the command handshake, where clk is the BIU clock and cclk_in is the CIU clock:
3 (clk) + 3 (cclk_in)

Once a command is accepted, you can send another command to the CIU-which has a one-deep command queue-under the following conditions:

- If the previous command was not a data transfer command, the new command is sent to the SD/MMC card once the previous command completes.
- If the previous command is a data transfer command and if wait_prvdata_complete (bit[13]) of the SDMMC_CMD register is set for the new command, the new command is sent to the SD/MMC card only when the data transfer completes.

If the wait_prvdata_complete is 0, then the new command is sent to the SD/MMC card as soon as the previous command is sent. Typically, you should use this only to stop or abort a previous data transfer or query the card status in the middle of a data transfer.

39.3.1.3 Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the controller raw interrupt status, the interrupt-mask register, and the global interrupt-enable register bit. Once an interrupt condition is detected, it sets the corresponding interrupt bit in the raw

Rockchip Confidential

interrupt status register SDMMC_RINTSTS. The raw interrupt status bit stays on until the software clears the bit by writing a 1 to the interrupt bit; a 0 leaves the bit untouched.
The interrupt port is an active-high, level-sensitive interrupt. The interrupt port is active only when any bit in the raw interrupt status register is active, the corresponding interrupt mask bit is 1, and the global interrupt enable bit is 1. The interrupt port is registered in order to avoid any combinational glitches.
The int_enable is reset to 0 on power-on, and the interrupt mask bits are set to 32'h0, which masks all the interrupts.

Notes:

Before enabling the interrupt, it is always recommended that you write 32'hffff_ffff to the raw interrupt status register in order to clear any pending unserviced interrupts. When clearing interrupts during normal operation, ensure that you clear only the interrupt bits that you serviced.

The SDIO Interrupts, Receive FIFO Data Request (RXDR), and Transmit FIFO Data Request (TXDR) are set by level-sensitive interrupt sources. Therefore, the interrupt source should be first cleared before you can clear the interrupt bit of the Raw Interrupt register. For example, on seeing the Receive FIFO Data Request (RXDR) interrupt, the FIFO should be emptied so that the "FIFO count greater than the RX-Watermark" condition, which triggers the interrupt, becomes inactive. The rest of the interrupts are triggered by a single clock-pulse-width source.

Table 39-1 Bits in Interrupt Status Register

Bits	Interrupt	Description
24	sdio_interrupt	Interrupt from SDIO card. In MMC-Ver3.3-only mode, these bits are always 0.
16	Card no-busy	If card exit busy status, the interrupt happened.
15	End Bit Error (read) / Write no CRC (EBE)	Error in end-bit during read operation, or no data CRC received during write operation. For MMC CMD19, there may be no CRC status returned by the card. Hence, EBE is set for CMD19. The application should not treat this as an error.
14	Auto Command Done (ACD)	Stop/abort commands automatically sent by card unit and not initiated by host; similar to Command Done (CD) interrupt. Recommendation: Software typically need not enable this for non CE-ATA accesses; Data Transfer Over (DTO) interrupt that comes after this interrupt determines whether data transfer has correctly competed.
13	Start Bit Error (SBE)	Error in data start bit when data is read from a card. In 4-bit mode, if DAT[0] line indicates start bit-that is, 0-and any of the other data bits do not have start bit, then this error is set. Busy Complete Interrupt when data is written to the card. This interrupt is generated after completion of busy driven by the card after the last data block is written into the card.
12	Hardware Locked write Error (HLE)	During hardware-lock period, write attempted to one of locked registers. When software sets the start_cmd bit in the SDMMC_CMD register, the Host Controller tries to load the command. If the command buffer is already filled with a command, this error is raised. The software then has to reload the command.
11	FIFO Underrun/ Overrun Error (FRUN)	Host tried to push data when FIFO was full, or host tried to read data when FIFO was empty. Typically this should not happen, except due to error in software. Card unit never pushes data into FIFO when FIFO is full, and pop data when FIFO is empty. If IDMAC is enabled, FIFO under-run/over-run can occur due to a programming error on MSIZE and

Rockchip Confidential

Bits	Interrupt	Description
		watermark values in SDMMC_FIFOTH register.
10	Data Starvation by Host Timeout (HTO)	To avoid data loss, card clock out is stopped if FIFO is empty when writing to card, or FIFO is full when reading from card. Whenever card clock is stopped to avoid data loss, data-starvation timeout counter is started with data-timeout value. This interrupt is set if host does not fill data into FIFO during write to card, or does not read from FIFO during read from card before timeout period. Even after timeout, card clock stays in stopped state, with CIU state machines waiting. It is responsibility of host to push or pop data into FIFO upon interrupt, which automatically restarts cclk_out and card state machines. Even if host wants to send stop/abort command, it still needs to ensure it has to push or pop FIFO so that clock starts in order for stop/abort command to send on command signal along with data that is sent or received on data line.
9	Data Read Timeout (DRTO)	In Normal functioning mode: Data read timeout (DRTO) Data timeout occurred. Data Transfer Over (DTO) also set if data timeout occurs. In Boot Mode: Boot Data Start (BDS) When set, indicates that Host Controller has started to receive boot data from the card. A write to this register with a value of 1 clears this interrupt.
8	Response Timeout (RTO)	In normal functioning mode: Response timeout (RTO) Response timeout occurred. Command Done (CD) also set if response timeout occurs. If command involves data transfer and when response times out, no data transfer is attempted by Host Controller. In Boot Mode: Boot Ack Received (BAR) When expect_boot_ack is set, on reception of a boot acknowledge pattern—0-1-0—this interrupt is asserted. A write to this register with a value of 1 clears this interrupt.
7	Data CRC Error (DCRC)	Received Data CRC does not match with locally-generated CRC in CIU. Can also occur if the Write CRC status is incorrectly sampled by the Host.
6	Response CRC Error (RCRC)	Response CRC does not match with locally-generated CRC in CIU.
5	Receive FIFO Data Request (RXDR)	Interrupt set during read operation from card when FIFO level is greater than Receive-Threshold level. Recommendation: In DMA modes, this interrupt should not be enabled. In non-DMA mode: pop RX_WMark + 1 data from FIFO.
4	Transmit FIFO Data Request (TXDR)	Interrupt set during write operation to card when FIFO level reaches less than or equal to Transmit-Threshold level. Recommendation: In DMA modes, this interrupt should not be enabled. In non-DMA mode: if (pending_bytes > (FIFO_DEPTH - TX_WMark))

Rockchip Confidential

Bits	Interrupt	Description
		push (FIFO_DEPTH - TX_WMark) data into FIFO else push pending_bytes data into FIFO
3	Data Transfer Over (DTO)	Indicates Data transfer completed. Though on detection of errors-Start Bit Error, Data CRC error, and so on, DTO may or may not be set; the application must issue CMD12, which ensures that DTO is set. Recommendation: In non-DMA mode, when data is read from card, on seeing interrupt, host should read any pending data from FIFO. In DMA mode, DMA controllers guarantee FIFO is flushed before interrupt. DTO bit is set at the end of the last data block, even if the device asserts MMC busy after the last data block.
2	Command Done(CD)	Command sent to card and got response from card, even if Response Error or CRC error occurs.
1	Response Error (RE)	Error in received response set if one of following occurs: ● Transmission bit != 0 ● Command index mismatch ● End-bit != 1
0	Card-Detect (CDT)	When one or more cards inserted or removed, this interrupt occurs. Software should read card-detect register to determine current card status. Recommendation: After power-on and before enabling interrupts, software should read card detect register and store it in memory. When interrupt occurs, it should read card detect register and compare it with value stored in memory to determine which card(s) were removed/inserted. Before exiting ISR, software should update memory with new card-detect value.

39.3.1.4 FIFO Controller Unit

The FIFO controller interfaces the external FIFO to the host interface and the card controller unit. When FIFO overrun and under-run conditions occur, the card clock stops in order to avoid data loss.

The FIFO uses a two-clock synchronous read and synchronous write dual-port RAM. One of the ports is connected to the host clock(clk), and the second port is connected to the card clock(cclk_in).

39.3.2 Card Interface Unit

The Card Interface Unit (CIU) interfaces with the Bus Interface Unit (BIU) and the external devices. The host writes command parameters to the BIU control registers, and these parameters are then passed to the CIU. Depending on control register values, the CIU generates SD/MMC command and data traffic on a selected card bus according to SD/MMC protocol. The Host Controller accordingly controls the command and data path.

The following software restrictions should be met for proper CIU operation:

- Only one data transfer command can be issued at a time.
- During an open-ended card write operation, if the card clock is stopped because the FIFO is empty, the software must first fill the data into the FIFO and start the card clock. It can then issue only a stop/abort command to the card.
- When issuing card reset commands (CMD0, CMD15 or CMD52_reset) while a card data

Rockchip Confidential

transfer is in progress, the software must set the stop_abort_cmd bit in the SDMMC_CMD register so that the Host Controller can stop the data transfer after issuing the card reset command.
- When the data end bit error is set in the SDMMC_RINTSTS register, the Host Controller does not guarantee SDIO interrupts. The software should ignore the SDIO interrupts and issue the stop/abort command to the card, so that the card stops sending the read data.
- If the card clock is stopped because the FIFO is full during a card read, the software should read at least two FIFO locations to start the card clock.

The CIU block consists of the following primary functional blocks:
- Command path
- Data path
- SDIO interrupt control
- Clock control
- Error detection

39.3.2.1 Command Path

The command path performs the following functions:
- Loads clock parameters
- Loads card command parameters
- Sends commands to card bus (ccmd_out line)
- Receives responses from card bus (ccmd_in line)
- Sends responses to BIU
- Drives the P-bit on command line

A new command is issued to the Host Controller by programming the BIU registers and setting the start_cmd bit in the SDMMC_CMD register. The BIU asserts start_cmd, which indicates that a new command is issued to the SD/MMC device. The command path loads this new command (command, command argument, timeout) and sends acknowledge to the BIU by asserting cmd_taken.
Once the new command is loaded, the command path state machine sends a command to the device bus-including the internally generated CRC7-and receives a response, if any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clocks before loading a new command.

Load Command Parameters

One of the following commands or responses is loaded in the command path:
- New command from BIU – When start_cmd is asserted, then the start_cmd bit is set in the SDMMC_CMD register.
- Internally generated auto-stop command – When the data path ends, the stop command request is loaded.
- IRQ response with RCA 0x000 – When the command path is waiting for an IRQ response from the MMC card and a "send irq response" request is signaled by the BIU, then the send_irq_response bit is set in the SDMMC_CTRL register.

Loading a new command from the BIU in the command path depends on the following SDMMC_CMD register bit settings:
- update_clock_registers_only – If this bit is set in the SDMMC_CMD register, the command path updates only the clock enable, clock divider, and clock source registers. If this bit is not set, the command path loads the command, command argument, and timeout registers; it then starts processing the new command.
- wait_prvdata_complete – If this bit is set, the command path loads the new command under one of the following conditions:
  - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (byte_count = 0).
  - After completion of the current data transfer, if a predefined data transfer is in progress.

Send Command and Receive Response

Once a new command is loaded in the command path, update_clock_registers_only bit is unset – the command path state machine sends out a command on the device bus; the command path state machine is illustrated in following figure.

Rockchip Confidential

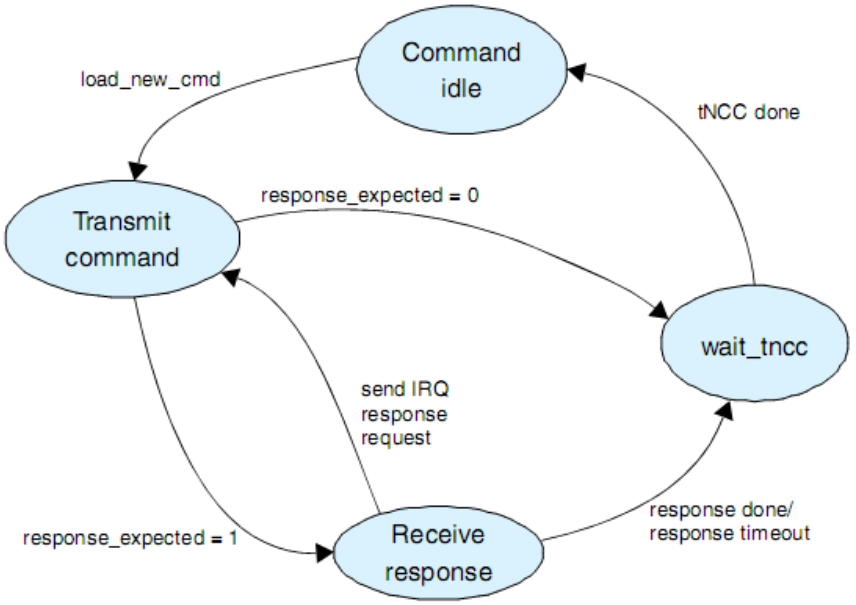

Fig. 39-2 Host Controller Command Path State Machine

The command path state machine performs the following functions, according to SDMMC_CMD register bit values:

- send_initialization – Initialization sequence of 80 clocks is sent before sending the command.
- response_expected – Response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start bit of the card response is not received within the number of clocks programmed in the timeout register, then the response timeout and command done bit is set in the Raw Interrupt Status register as a signal to the BIU. If the response-expected bit is not set, the command path sends out a command and signals a response done to the BIU; that is, the command done bit is set in the Raw Interrupt Status register.
- response_length – If this bit is set, a 136-bit response is received; if it is not set, a 48-bit response is received.
- check_response_crc – If this bit is set, the command path compares CRC7 received in the response with the internally-generated CRC7. If the two do not match, the response CRC error is signaled to the BIU; that is, the response CRC error bit is set in the Raw Interrupt Status register SDMMC_RINTSTS.

Send Response to BIU

If the response_expected bit is set in the SDMMC_CMD register, the received response is sent to the BIU. The Response0 register is updated for a short response, and the Response3, Response2, Response1, and Response0 registers are updated on a long response, after which the Command Done bit is set. If the response is for an auto_stop command sent by the CIU, the response is saved in the Response1 register, after which the Auto Command Done bit is set.

Additionally, the command path checks for the following:

- Transmission bit = 0
- Command index matches command index of the sent command
- End bit = 1 in received card response

The command index is not checked for a 136-bit response or if the check_response_crc bit is unset. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved-that is, 111111.

Polling Command Completion Signal

The device generates the Command Completion Signal in order to notify the host controller of the normal command completion or command termination.

Command Completion Signal Detection and Interrupt to Host Processor

If the ccs_expected bit is set in the SDMMC_CMD register, the Command Completion Signal (CCS) from the device is indicated by setting the Data Transfer Over (DTO) bit in the

Rockchip Confidential

SDMMC_RINTSTS register. The Host Controller generates a Data Transfer Over (DTO) interrupt if this interrupt is not masked.

Command Completion Signal Timeout

If the command expects a CCS from the device—if the ccs_expected bit is set in the SDMMC_CMD register—the command state machine waits for the CCS and remains in a wait_CCSS state. If the device fails to send out the CCS, the host software should implement a timeout mechanism to free the command and data path. The host controller does not implement a hardware timer; it is the responsibility of the host software to maintain a software timer.

In the event of a CCS timeout, the host should issue a CCSD by setting the send_ccsd bit in the CTRL register. The host controller command state machine sends the CCSD to the device and exits to an idle state. After sending the CCSD, the host should also send a CMD12 to the device in order to abort the outstanding command.

Send Command Completion Signal Disable

If the send_ccsd bit is set in the SDMMC_CTRL register, the host sends a Command Completion Signal Disable (CCSD) pattern on the CMD line. The host can send the CCSD while waiting for the CCS or after a CCS timeout happens.

After sending the CCSD pattern, the host sets the Command Done (CD) bit in SDMMC_RINTSTS and also generates an interrupt to the host if the Command Done interrupt is not masked.

39.3.2.2 Data Path

The data path block pops the data FIFO and transmits data on cdata_out during a write data transfer, or it receives data on cdata_in and pushes it into the FIFO during a read data transfer. The data path loads new data parameters—that is, data expected, read/write data transfer, stream/block transfer, block size, byte count, card type, timeout registers—whenever a data transfer command is not in progress.

If the data_expected bit is set in the SDMMC_CMD register, the new command is a data transfer command and the data path starts one of the following:

- Transmit data if the read/write bit = 1
- Data receive if read/write bit = 0

Data Transmit

The data transmit state machine, illustrated in following figure, starts data transmission two clocks after a response for the data write command is received; this occurs even if the command path detects a response error or response CRC error. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the transfer_mode bit in the SDMMC_CMD register, the data transmit state machine puts data on the card data bus in a stream or in block(s).

Rockchip Confidential

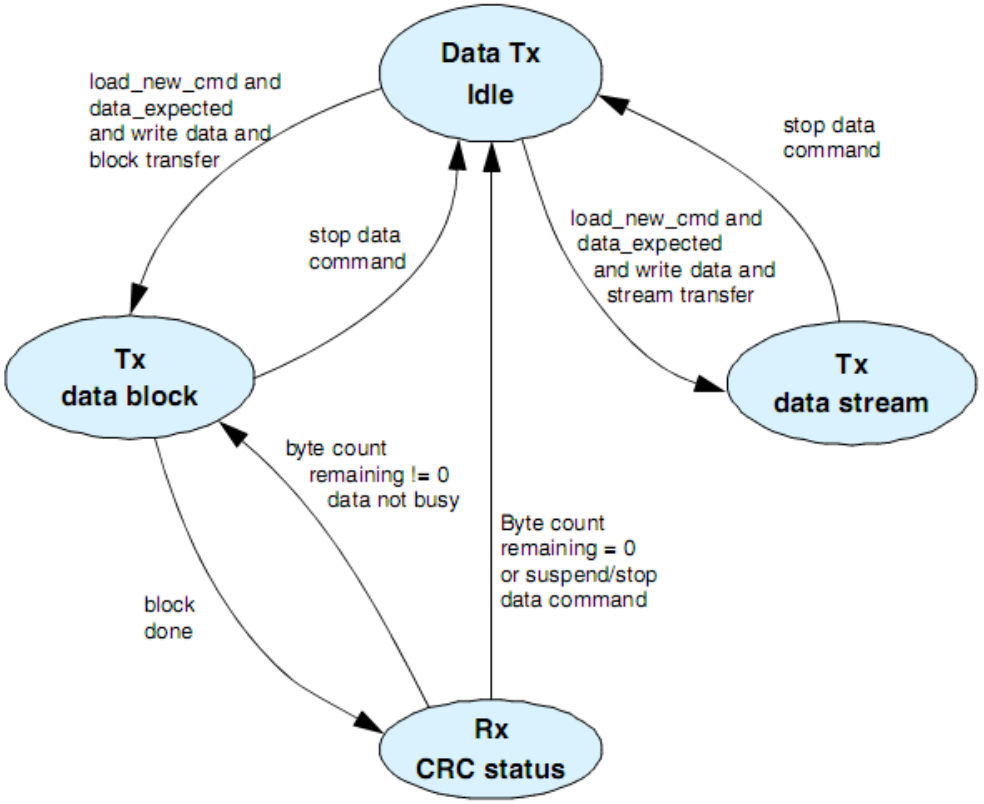

Fig. 39-3 Host Controller Data Transmit State Machine

Stream Data Transmit

If the transfer_mode bit in the SDMMC_CMD register is set to 1, it is a stream-write data transfer. The data path pops the FIFO from the BIU and transmits in a stream to the card data bus. If the FIFO becomes empty, the card clock is stopped and restarted once data is available in the FIFO.

If the byte_count register is programmed to 0, it is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues a stop command. A stream data transfer is terminated when the end bit of the stop command and end bit of the data match over two clocks.

If the byte_count register is programmed with a non-zero value and the send_auto_stop bit is set in the SDMMC_CMD register, the stop command is internally generated and loaded in the command path when the end bit of the stop command occurs after the last byte of the stream write transfer matches.

This data transfer can also terminate if the host issues a stop command before all the data bytes are transferred to the card bus.

Single Block Data

If the transfer_mode bit in the SDMMC_CMD register is set to 0 and the byte_count register value is equal to the value of the block_size register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated CRC16.

If the SDMMC_CTYPE register bit for the selected card – indicated by the card_num value in the SDMMC_CMD register – is set for a 1-bit, 4-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU; this happens when the data-transfer-over bit is set in the SDMMC_RINTSTS register.

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the data CRC error bit in the SDMMC_RINTSTS register.

Additionally, if the start bit of the CRC status is not received by two clocks after the end of the data block, a CRC status start bit error is signaled to the BIU by setting the write-no-CRC bit in the SDMMC_RINTSTS register.

Rockchip Confidential

Multiple Block Data

A multiple-block write-data transfer occurs if the transfer_mode bit in the SDMMC_CMD register is set to 0 and the value in the byte_count register is not equal to the value of the block_size register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC16. If the SDMMC_CTYPE register bit for the selected card – indicated by the card_num value in the SDMMC_CMD register – is set to 1-bit, 4-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC16 is separately generated and transmitted on 1, 4, or 8 data lines, respectively.

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining byte_count becomes 0, the data path signals to the BIU that the data transfer is done; this happens when the data-transfer-over bit is set in the SDMMC_RINTSTS register.

If the remaining data bytes are greater than 0, the data path state machine starts to transmit another data block.

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the data CRC error bit in the SDMMC_RINTSTS register, and continues further data transmission until all the bytes are transmitted.

Additionally, if the CRC status start bit is not received by two clocks after the end of a data block, a CRC status start bit error is signaled to the BIU by setting the write-no-CRC bit in the SDMMC_RINTSTS register; further data transfer is terminated.

If the send_auto_stop bit is set in the SDMMC_CMD register, the stop command is internally generated during the transfer of the last data block, where no extra bytes are transferred to the card. The end bit of the stop command may not exactly match the end bit of the CRC status in the last data block.

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, respectively, the data transmit state machine terminates the data transfer when all the data is transferred, at which time the internally generated stop command is loaded in the command path.

If the byte_count is 0 – the block size must be greater than 0 – it is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues a stop or abort command.

Data Receive

The data-receive state machine, illustrated in following figure, receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. If a response is not received from the card because a response timeout occurs, the BIU does not receive a signal that the data transfer is complete; this happens if the command sent by the Host Controller is an illegal operation for the card, which keeps the card from starting a read data transfer.

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the transfer_mode bit in the SDMMC_CMD register, the data-receive state machine gets data from the card data bus in a stream or block(s).

Rockchip Confidential

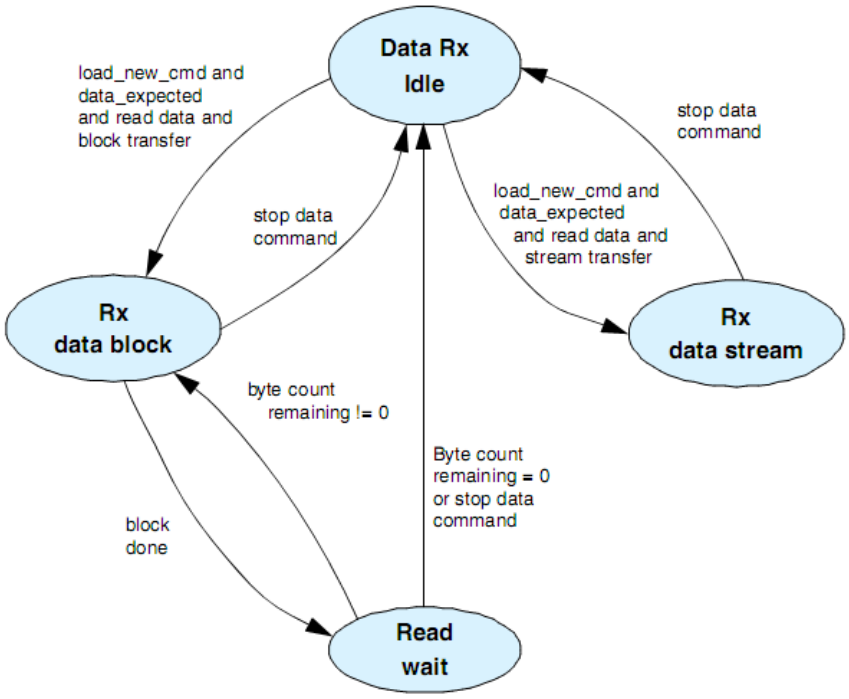

Fig. 39-4 Host Controller Data Receive State Machine

Stream Data Read

A stream-read data transfer occurs if the transfer_mode bit in the SDMMC_CMD register equals 1, at which time the data path receives data from the card and pushes it to the FIFO. If the FIFO becomes full, the card clock stops and restarts once the FIFO is no longer full.

An open-ended stream-read data transfer occurs if the byte_count register equals 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues a stop command. A stream data transfer terminates two clock cycles after the end bit of the stop command.

If the byte_count register contains a non-zero value and the send_auto_stop bit is set in the SDMMC_CMD register, a stop command is internally generated and loaded into the command path, where the end bit of the stop command occurs after the last byte of the stream data transfer is received. This data transfer can terminate if the host issues a stop or abort command before all the data bytes are received from the card.

Single-Block Data Read

A single-block read-data transfer occurs if the transfer_mode bit in the SDMMC_CMD register is set to 0 and the value of the byte_count register is equal to the value of the block_size register. When a start bit is received before the data times out, data bytes equal to the block size and CRC16 are received and checked with the internally-generated CRC16. If the SDMMC_CTYPE register bit for the selected card – indicated by the card_num value in the SDMMC_CMD register – is set to a 1-bit, 4-bit transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there is a CRC16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an end-bit error.

Multiple-Block Data Read

If the transfer_mode bit in the SDMMC_CMD register is set to 0 and the value of the byte_count register is not equal to the value of the block_size register, it is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC16.

If the SDMMC_CTYPE register bit for the selected card – indicated by the card_num value in the SDMMC_CMD register – is set to a 1-bit, 4-bit data transfer, data is received from 1, 4 data lines, respectively, and CRC16 is separately generated and checked for 1, 4 data lines, respectively.

After a data block is received, if the remaining byte_count becomes 0, the data path signals a data transfer to the BIU.

Rockchip Confidential

If the remaining data bytes are greater than 0, the data path state machine causes another data block to be received. If CRC16 of a received data block does not match the internally-generated CRC16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted.
Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU and the data-receive state machine terminates data reception, waits for data timeout, and signals to the BIU that the data transfer is complete.
If the send_auto_stop bit is set in the SDMMC_CMD register, the stop command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card; the end bit of the stop command may not exactly match the end bit of the last data block.
If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data is transferred, at which point the internally-generated stop command is loaded in the command path. Data received from the card after that are then ignored by the data path.
If the byte_count is 0—the block size must be greater than 0—it is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues a stop or abort command.

Auto-Stop

The Host Controller internally generates a stop command and is loaded in the command path when the send_auto_stop bit is set in the SDMMC_CMD register.
The software should set the send_auto_stop bit according to details listed in following table.

Table 39-2 Auto-Stop Generation

Card type	Transfer type	Byte Count	send_auto_stop bit set	Comments
MMC	Stream read	0	No	Open-ended stream
MMC	Stream read	>0	Yes	Auto-stop after all bytes transfer
MMC	Stream write	0	No	Open-ended stream
MMC	Stream write	>0	Yes	Auto-stop after all bytes transfer
MMC	Single-block read	>0	No	Byte count =0 is illegal
MMC	Single-block write	>0	No	Byte count =0 is illegal
MMC	Multiple-block read	0	No	Open-ended multiple block
MMC	Multiple-block read	>0	Yes①	Pre-defined multiple block
MMC	Multiple-block write	0	No	Open-ended multiple block
MMC	Multiple-block write	>0	Yes①	Pre-defined multiple block
SDMEM	Single-block read	>0	No	Byte count =0 is illegal
SDMEM	Single-block write	>0	No	Byte count =0 illegal
SDMEM	Multiple-block read	0	No	Open-ended multiple block
SDMEM	Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
SDMEM	Multiple-block write	0	No	Open-ended multiple block
SDMEM	Multiple-block write	>0	Yes	Auto-stop after all bytes transfer
SDIO	Single-block read	>0	No	Byte count =0 is illegal
SDIO	Single-block write	>0	No	Byte count =0 illegal
SDIO	Multiple-block read	0	No	Open-ended multiple block

Rockchip Confidential

Card type	Transfer type	Byte Count	send_auto_stop bit set	Comments
SDIO	Multiple-block read	>0	No	Pre-defined multiple block
SDIO	Multiple-block write	0	No	Open-ended multiple block
SDIO	Multiple-block write	>0	No	Pre-defined multiple block

*①:The condition under which the transfer mode is set to block transfer and byte_count is equal to block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n*block_size (n = 2, 3, …), the condition is treated as a predefined multiple-block data transfer command. In the case of an MMC card, the host software can perform a predefined data transfer in two ways: 1) Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue MD18/CMD25 commands without setting the send_auto_stop bit. 2) Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the send_auto_stop bit set. In this case, the multiple-block data transfer is terminated by an internally-generated auto-stop command after the programmed byte count.*

The following list conditions for the auto-stop command.

- Stream read for MMC card with byte count greater than 0 – The Host Controller generates an internal stop command and loads it into the command path so that the end bit of the stop command is sent out when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than 6 (48 bits), a few extra data bytes are received from the card before the end bit of the stop command is sent.
- Stream write for MMC card with byte count greater than 0 - The Host Controller generates an internal stop command and loads it into the command path so that the end bit of the stop command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than 6 (48 bits), the data path transmits the data last in order to meet the above condition.
- Multiple-block read memory for SD card with byte count greater than 0 – If the block size is less than 4 (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus), the auto-stop command is loaded in the command path after all the bytes are read. Otherwise, the top command is loaded in the command path so that the end bit of the stop command is sent after the last data block is received.
- Multiple-block write memory for SD card with byte count greater than 0 – If the block size is less than 3 (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the auto-stop command is loaded in the command path after all data blocks are transmitted. Otherwise, the stop command is loaded in the command path so that the end bit of the stop command is sent after the end bit of the CRC status is received.

Precaution for host software during auto-stop – Whenever an auto-stop command is issued, the host software should not issue a new command to the SD/MMC device until the auto-stop is sent by the Host Controller and the data transfer is complete. If the host issues a new command during a data transfer with the auto-stop in progress, an auto-stop command may be sent after the new command is sent and its response is received; this can delay sending the stop command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue a stop or abort command, in which case the Host Controller does not generate an auto-stop command.

39.3.2.3 Non-Data Transfer Commands that Use Data Path

Some non-data transfer commands (non-read/write commands) also use the data path. Following table lists the commands and register programming requirements for them.

Table 39-3 Non-data Transfer Commands and Requirements

Base Address [12:8]	CMD 27	CMD 30	CMD 42	ACMD 13	ACMD 22	ACMD 51
SDMMC_CMD register programming						
cmd_index	6'h1B	6'h1E	6'h2A	6'h0D	6'h16	6'h33
response_expect	1	1	1	1	1	1
rResponse_length	0	0	0	0	0	0

Rockchip Confidential

Base Address [12:8]	CMD 27	CMD 30	CMD 42	ACMD 13	ACMD 22	ACMD 51

data_expected	1	1	1	1	1	1
read/write	1	0	1	0	0	0
transfer_mode	0	0	0	0	0	0
send_auto_stop	0	0	0	0	0	0
wait_prevdata_complete	0	0	0	0	0	0
stop_abort_cmd	0	0	0	0	0	0
Command Argument register programming						
	stuff bits	32-bit write protect data address	stuff bits	stuff bits	stuff bits	stuff bits
Block Size register programming						
	16	4	Num_bytes①	64	4	8
Byte Count register programming						
	16	4	Num_bytes①	64	4	8

①: Num_bytes = No. of bytes specified as per the lock card data structure (Refer to the SD specification and the MMC specification)

39.3.2.4 SDIO Interrupt Control

Interrupts for SD cards are reported to the BIU by asserting an interrupt signal for two clock cycles. SDIO cards signal an interrupt by asserting cdata_in low during the interrupt period; an interrupt period for the selected card is determined by the interrupt control state machine. An interrupt period is always valid for non-active or non-selected cards, and 1-bit data mode for the selected card. An interrupt period for a wide-bus active or selected card is valid for the following conditions:

- Card is idle
- Non-data transfer command in progress
- Third clock after end bit of data block between two data blocks
- From two clocks after end bit of last data until end bit of next data transfer command

Bear in mind that, in the following situations, the controller does not sample the SDIO interrupt of the selected card when the card data width is 4 bits. Since the SDIO interrupt is level-triggered, it is sampled in a further interrupt period and the host does not lose any SDIO interrupt from the card.

- Read/Write Resume – The CIU treats the resume command as a normal data transfer command. SDIO interrupts during the resume command are handled similarly to other data commands. According to the SDIO specification, for the normal data command the interrupt period ends after the command end bit of the data command; for the resume command, it ends after the response end bit. In the case of the resume command, the Controller stops the interrupt sampling period after the resume command end bit, instead of stopping after the response end bit of the resume command.

Suspend during read transfer – If the read data transfer is suspended by the host, the host sets the abort_read_data bit in the controller to reset the data state machine. In the CIU, the SDIO interrupts are handled such that the interrupt sampling starts after the abort_read_data bit is set by the host. In this case the controller does not sample SDIO interrupts between the period from response of the suspend command to setting the abort_read_data bit, and starts sampling after setting the abort_read_data bit.

39.3.2.5 Clock Control

The clock control block provides different clock frequencies required for SD/MMC cards. The cclk_in signal is the source clock (cclk_in >= card max operating frequency) for clock divider of the clock control block. This source clock (cclk_in) is used to generate different card clock frequencies (cclk_out). The card clock can have different clock frequencies, since the card can be a low-speed card or a full-speed card. The Host Controller provides one clock signal (cclk_out).

The clock frequency of a card depends on the following clock control registers:

Rockchip Confidential

- Clock Divider register – Internal clock dividers are used to generate different clock frequencies required for card. The division factor for each clock divider can be programmed by writing to the Clock Divider register. A value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2.
- Clock Control register – cclk_out can be enabled or disabled for each card under the following conditions:
  - clk_enable – cclk_out for a card is enabled if the clk_enable bit for a card in the Clock Control register is programmed (set to 1) or disabled (set to 0).
  - Low-power mode – Low-power mode of a card can be enabled by setting the low-power mode bit of the Clock Control register to 1. If low-power mode is enabled to save card power, the cclk_out is disabled when the card is idle for at least 8 card clock cycles. It is enabled when a new command is loaded and the command path goes to a non-idle state.

Additionally, cclk_out is disabled when an internal FIFO is full – card read (no more data can be received from card) – or when the FIFO is empty – card write (no data is available for transmission). This helps to avoid FIFO overrun and underrun conditions. It is used by the command and data path to qualify cclk_in for driving outputs and sampling inputs at the programmed clock frequency for the selected card, according to the Clock Divider and Clock Source register values.

Under the following conditions, the card clock is stopped or disabled, along with the active clk_en, for the selected card:

- Clock can be disabled by writing to Clock Enable register (clk_en bit = 1).
- If low-power mode is selected and card is idle, or not selected for 8 clocks.
- FIFO is full and data path cannot accept more data from the card and data transfer is incomplete –to avoid FIFO overrun.

FIFO is empty and data path cannot transmit more data to the card and data transfer is incomplete – to avoid FIFO underrun.

39.3.2.6 Error Detection

- Response
  - Response timeout – Response expected with response start bit is not received within programmed number of clocks in timeout register.
  - Response CRC error – Response is expected and check response CRC requested; response CRC7 does not match with the internally-generated CRC7.
  - Response error – Response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.
- Data transmit
  - No CRC status – During a write data transfer, if the CRC status start bit is not received two clocks after the end bit of the data block is sent out, the data path does the following:
    - Signals no CRC status error to the BIU
    - Terminates further data transfer
    - Signals data transfer done to the BIU
  - Negative CRC – If the CRC status received after the write data block is negative (that is, not 010), a data CRC error is signaled to the BIU and further data transfer is continued.
  - Data starvation due to empty FIFO – If the FIFO becomes empty during a write data transmission, or if the card clock is stopped and the FIFO remains empty for data timeout clocks, then a data-starvation error is signaled to the BIU and the data path continues to wait for data in the FIFO.
- Data receive
  - Data timeout – During a read-data transfer, if the data start bit is not received before the number of clocks that were programmed in the timeout register, the data path does the following:
    - Signals data-timeout error to the BIU
    - Terminates further data transfer
    - Signals data transfer done to BIU
  - Data start bit error – During a 4-bit or 8-bit read-data transfer, if the all-bit data

Rockchip Confidential

line does not have a start bit, the data path signals a data start bit error to the BIU and waits for a data timeout, after which it signals that the data transfer is done.

- Data CRC error – During a read-data-block transfer, if the CRC16 received does not match with the internally generated CRC16, the data path signals a data CRC error to the BIU and continues further data transfer.
- Data end-bit error – During a read-data transfer, if the end bit of the received data is not 1, the data path signals an end-bit error to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.

Data starvation due to FIFO full – During a read data transmission and when the FIFO becomes full, the card clock is stopped. If the FIFO remains full for data timeout clocks, a data starvation error is signaled to the BIU (Data Starvation by Host Timeout bit is set in SDMMC_RINTSTS register) and the data path continues to wait for the FIFO to start to empty.

39.3.3 Internal Direct Memory Access Controller (IDMAC)

The Internal Direct Memory Access Controller (IDMAC) has a Control and Status Register (CSR) and a single Transmit/Receive engine, which transfers data from host memory to the device port and vice versa. The controller utilizes a descriptor to efficiently move data from source to destination with minimal Host CPU intervention. You can program the controller to interrupt the Host CPU in situations such as data Transmit and Receive transfer completion from the card, as well as other normal or error conditions.

The IDMAC and the Host driver communicate through a single data structure. CSR addresses 0x80 to 0x98 are reserved for host programming.

The IDMAC transfers the data received from the card to the Data Buffer in the Host memory, and it transfers Transmit data from the Data Buffer in the Host memory to the FIFO. Descriptors that reside in the Host memory act as pointers to these buffers.

A data buffer resides in physical memory space of the Host and consists of complete data or partial data. Buffers contain only data, while buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data.

A single descriptor is used for both reception and transmission. The base address of the list is written into Descriptor List Base Address Register (SDMMC_DBADDR @0x88). A descriptor list is forward linked. The Last Descriptor can point back to the first entry in order to create a ring structure. The descriptor list resides in the physical memory address space of the Host. Each descriptor can point to a maximum of two data buffers.

39.3.3.1 IDMAC CSR Access

When an IDMAC is introduced, an additional CSR space resides in the IDMAC that controls the IDMAC functionality. The host accesses the new CSR space in addition to the existing control register set in the BIU. The IDMAC CSR primarily contains descriptor information. For a write operation to the CSR, the respective CSR logic of the IDMAC and BIU decodes the address before accepting. For a read operation from the CSR, the appropriate CSR read path is enabled.

You can enable or disable the IDMAC operation by programming bit[25] in the SDMMC_CTRL register of the BIU. This allows the data transfer by accessing the slave interface on the AMBA bus if the IDMAC is present but disabled. When IDMAC is enabled, the FIFO cannot be accessed through the slave interface.

39.3.3.2 Descriptors

- Descriptor structures

The IDMAC uses these types of descriptor structures:

- Dual-Buffer Structure – The distance between two descriptors is determined by the Skip Length value programmed in the Descriptor Skip Length (DSL) field of the Bus Mode Register (SDMMC_BMOD @0x80).

Rockchip Confidential

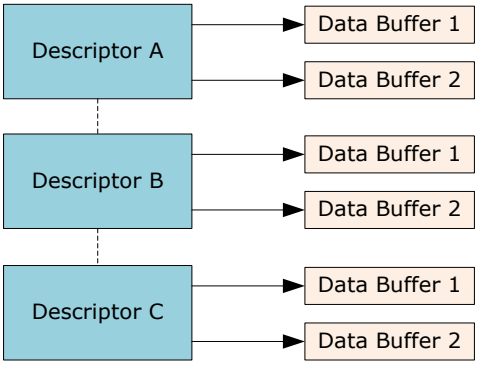

Fig. 39-5 Dual-Buffer Descriptor Structure

- Chain Structure – Each descriptor points to a unique buffer and the next descriptor.

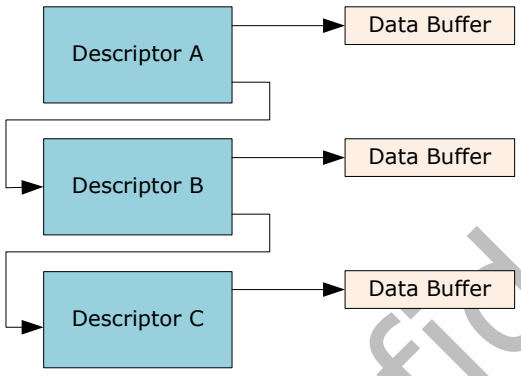

Fig. 39-6 Chain Descriptor Structure

- Descriptor formats

Following figure illustrates the internal formats of a descriptor. The descriptor addresses must be aligned to the bus width used for 32-bit AHB data buses. Each descriptor contains 16 bytes of control and status information. DES0 is a notation used to denote the [31:0] bits, DES1 to denote [63:32] bits, DES2 to denote [95:64] bits, DES3 to denote [127:96] bits.

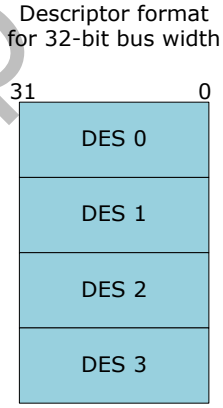

Fig. 39-7 Descriptor Formats for 32-bit AHB Address Bus Width

- The DES0 element in the IDMAC contains control and status information.

Table 39-4 Bits in IDMAC DES0 Element

Bit	Name	Description
31	OWN	When set, this bit indicates that the descriptor is owned by the IDMAC. When this bit is reset, it indicates that the descriptor is owned by the Host. The IDMAC clears this bit when it completes the data transfer.
30	Card Error Summary (CES)	These error bits indicate the status of the transaction to or from the card. These bits are also present in SDMMC_RINTSTS Indicates the logical OR of the following bits:

Rockchip Confidential

Bit	Name	Description
		● EBE: End Bit Error ● RTO: Response Time out ● RCRC: Response CRC ● SBE: Start Bit Error ● DRTO: Data Read Timeout ● DCRC: Data CRC for Receive ● RE: Response Error
29:6	Reserved	-
5	End of Ring (ER)	When set, this bit indicates that the descriptor list reached its final descriptor. The IDMAC returns to the base address of the list, creating a Descriptor Ring. This is meaningful for only a dual-buffer descriptor structure.
4	Second Address Chained (CH)	When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is set, BS2 (DES1[25:13]) should be all zeros.
3	First Descriptor (FS)	When set, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next Descriptor contains the beginning of the data.
2	Last Descriptor (LD)	This bit is associated with the last block of a DMA transfer. When set, the bit indicates that the buffers pointed to by this descriptor are the last buffers of the data. After this descriptor is completed, the remaining byte count is 0. In other words, after the descriptor with the LD bit set is completed, the remaining byte count should be 0.
1	Disable Interrupt on Completion (DIC)	When set, this bit will prevent the setting of the TI/RI bit of the IDMAC Status Register (IDSTS) for the data that ends in the buffer pointed to by this descriptor.
0	Reserved	-

■ The DES1 element contains the buffer size.

Table 39-5 Bits in IDMAC DES1 Element

Bit	Name	Description
31:26	Reserved	-
25:13	Buffer 2 Size (BS2)	These bits indicate the second data buffer byte size. The buffer size must be a multiple of 2, 4, or 8, depending upon the bus widths—16, 32, and 64 respectively. In the case where the buffer size is not a multiple of 2, 4, or 8, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and proceeds to the next buffer in case of a dual-buffer structure. This field is not valid for chain structure; that is, if DES0[4] is set.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size, which must be a multiple of 2, 4, or 8 bytes, depending upon the bus widths—16, 32, and 64, respectively. In the case where the buffer size is not a multiple of 2, 4, or 8, the resulting behavior is undefined. This field should not be zero. Note: If there is only one buffer to be programmed, you need to use only the Buffer 1, and not Buffer 2.

■ The DES2 element contains the address pointer to the data buffer.

Table 39-6 Bits in IDMAC DES2 Element

Bit	Name	Description
31:26	Reserved	
25:13	Buffer 2 Size (BS2)	These bits indicate the second data buffer byte size. The buffer size must be a multiple of 2, 4, or 8, depending upon the bus widths—16, 32, and 64 respectively. In the case where the

Rockchip Confidential

Bit	Name	Description
		buffer size is not a multiple of 2, 4, or 8, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and proceeds to the next buffer in case of a dual-buffer structure. This field is not valid for chain structure; that is, if DES0[4] is set.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size, which must be a multiple of 2, 4, or 8 bytes, depending upon the bus widths—16, 32, and 64, respectively. In the case where the buffer size is not a multiple of 2, 4, or 8, the resulting behavior is undefined. This field should not be zero. Note: If there is only one buffer to be programmed, you need to use only the Buffer 1, and not Buffer 2.

- The DES3 element contains the address pointer to the next descriptor if the present descriptor is not the last descriptor in a chained descriptor structure or the second buffer address for a dual-buffer structure.

Table 39-7 Bits in IDMAC DES3 Element

Bit	Name	Description
31:0	Buffer Address Pointer 2/ Next Descriptor Address (BAP2)	These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set, then this address contains the pointer to the physical memory where the Next Descriptor is present. If this is not the last descriptor, then the Next Descriptor address pointer must be bus-width aligned.

39.3.3.3 Initialization

IDMAC initialization occurs as follows:

1) Write to IDMAC Bus Mode Register—SDMMC_BMOD to set Host bus access parameters.
2) Write to IDMAC Interrupt Enable Register—SDMMC_IDINTEN to mask unnecessary interrupt causes.
3) The software driver creates either the Transmit or the Receive descriptor list. Then it writes to IDMAC Descriptor List Base Address Register (SDMMC_DBADDR), providing the IDMAC with the starting address of the list.
4) The IDMAC engine attempts to acquire descriptors from the descriptor lists.

- Host Bus Burst Access

The IDMAC attempts to execute fixed-length burst transfers on the AHB Master interface if configured using the FB bit of the IDMAC Bus Mode register. The maximum burst length is indicated and limited by the PBL field. The descriptors are always accessed in the maximum possible burst-size for the 16-bytes to be read— 16*8/bus-width.

The IDMAC initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO or the number of bytes to the end of data, when less than the configured burst-length.

The IDMAC indicates the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length bursts, then it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. Otherwise, in no fixed-length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.

- Host Data Buffer Alignment

The Transmit and Receive data buffers in host memory must be aligned, depending on the data width.

- Buffer Size Calculations

The driver knows the amount of data to transmit or receive. For transmitting to the card, the IDMAC transfers the exact number of bytes to the FIFO, indicated by the buffer size field of DES1.

If a descriptor is not marked as last-LS bit of DES0-then the corresponding buffer(s) of the descriptor are full, and the amount of valid data in a buffer is accurately indicated by its buffer size field. If a descriptor is marked as last, then the buffer cannot be full, as

Rockchip Confidential

indicated by the buffer size in DES1. The driver is aware of the number of locations that are valid in this case.

- Transmission

IDMAC transmission occurs as follows:

1) The Host sets up the elements (DES0-DES3) for transmission and sets the OWN bit (DES0[31]). The Host also prepares the data buffer.
2) The Host programs the write data command in the SDMMC_CMD register in BIU.
3) The Host will also program the required transmit threshold level (TX_WMark field in SDMMC_FIFOTH register).
4) The IDMAC determines that a write data transfer needs to be done as a consequence of step 2.
5) The IDMAC engine fetches the descriptor and checks the OWN bit. If the OWN bit is not set, it means that the host owns the descriptor. In this case the IDMAC enters suspend state and asserts the Descriptor Unable interrupt in the SDMMC_IDSTS register. In such a case, the host needs to release the IDMAC by writing any value to the poll demand register.
6) It will then wait for Command Done (CD) bit and no errors from BIU which indicates that a transfer can be done.
7) The IDMAC engine will now wait for a DMA interface request from BIU. This request will be generated based on the programmed transmit threshold value. For the last bytes of data which can't be accessed using a burst, SINGLE transfers are performed on AHB Master Interface.
8) The IDMAC fetches the Transmit data from the data buffer in the Host memory and transfers to the FIFO for transmission to card.
9) When data spans across multiple descriptors, the IDMAC will fetch the next descriptor and continue with its operation with the next descriptor. The Last Descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.
10) When data transmission is complete, status information is updated in SDMMC_IDSTS register by setting Transmit Interrupt, if enabled. Also, the OWN bit is cleared by the IDMAC by performing a write transaction to DES0.

- Reception

IDMAC reception occurs as follows:

1) The Host sets up the element (DES0-DES3) for reception, sets the OWN (DES0[31]).
2) The Host programs the read data command in the SDMMC_CMD register in BIU.
3) The Host will program the required receive threshold level (RX_WMark field in FIFOTH register).
4) The IDMAC determines that a read data transfer needs to be done as a consequence of step 2.
5) The IDMAC engine fetches the descriptor and checks the OWN bit. If the OWN bit is not set, it means that the host owns the descriptor. In this case the DMA enters suspend state and asserts the Descriptor Unable interrupt in the SDMMC_IDSTS register. In such a case, the host needs to release the IDMAC by writing any value to the poll demand register.
6) It will then wait for Command Done (CD) bit and no errors from BIU which indicates that a transfer can be done.
7) The IDMAC engine will now wait for a DMA interface request from BIU. This request will be generated based on the programmed receive threshold value. For the last bytes of data which can't be accessed using a burst, SINGLE transfers are performed on AHB.
8) The IDMAC fetches the data from the FIFO and transfer to Host memory.
9) When data spans across multiple descriptors, the IDMAC will fetch the next descriptor and continue with its operation with the next descriptor. The Last Descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.
10) When data reception is complete, status information is updated in SDMMC_IDSTS register by setting Receive Interrupt, if enabled. Also, the OWN bit is cleared by the IDMAC by performing a write transaction to DES0.

- Interrupts

Interrupts can be generated as a result of various events. SDMMC_IDSTS register contains

Rockchip Confidential

all the bits that might cause an interrupt. SDMMC_IDINTEN register contains an Enable bit for each of the events that can cause an interrupt.
There are two groups of summary interrupts-Normal and Abnormal-as outlined in SDMMC_IDSTS register. Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the interrupt signal dmac_intr_o is de-asserted.
Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Receive Interrupt—SDMMC_IDSTS[1] indicates that one or more data was transferred to the Host buffer.
An interrupt is generated only once for simultaneous, multiple events. The driver must scan SDMMC_IDSTS register for the interrupt cause.

39.3.3.4 Variable Delay/Clock Generation Unit

Variable delay mechanism for the cclk_in_drv is useful in order to meet a range of hold-time requirements across modes. Variable delay mechanism for the cclk_in_sample is mandatory and is required to achieve the correct sampling point for data.
The Clock Generation Unit (CLKGEN) includes Phase Shift Unit and Delay Line Unit.
The Phase Shift Unit can shift cclk_in_sample/cclk_in_drv by 0/90/180/270-degree relative to cclk_in. The Delay Line Unit can shift cclk_in_sample/cclk_in_drv step by step in the unit of delay element. The delay value range is 21ps~48ps for every delay element; the max delay element number is 128.
The architecture is as follows.

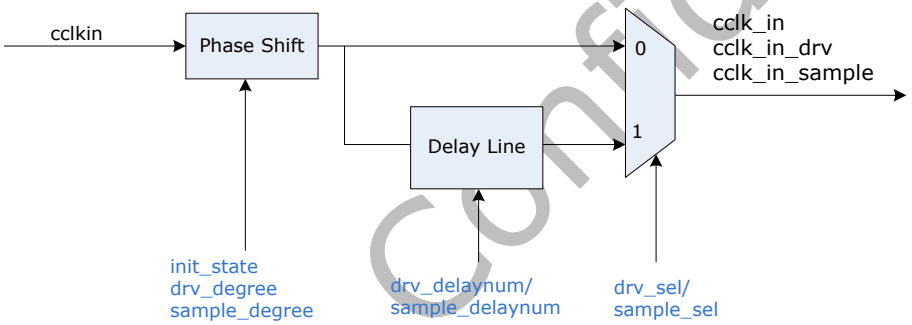

Fig. 39-8 Clock Generation Unit

39.4 Register Description

39.4.1 Registers Summary

Name	Offset	Size	Reset Value	Description
SDMMC_CTRL	0x0000	W	0x00000000	Control register
SDMMC_PWREN	0x0004	W	0x00000000	Power enable register
SDMMC_CLKDIV	0x0008	W	0x00000000	Clock divider register
SDMMC_CLKSRC	0x000C	W	0x00000000	SD clock source register
SDMMC_CLKENA	0x0010	W	0x00000000	Clock enable register
SDMMC_TMOUT	0x0014	W	0xFFFFFF40	Timeout register
SDMMC_CTYPE	0x0018	W	0x00000000	Card type register
SDMMC_BLKSIZ	0x001C	W	0x00000200	Block size register
SDMMC_BYTCNT	0x0020	W	0x00000200	Byte count register
SDMMC_INTMASK	0x0024	W	0x00000000	Interrupt mask register
SDMMC_CMDARG	0x0028	W	0x00000000	Command argument register
SDMMC_CMD	0x002C	W	0x20000000	Command register
SDMMC_RESP0	0x0030	W	0x00000000	Response register 0
SDMMC_RESP1	0x0034	W	0x00000000	Response register 1
SDMMC_RESP2	0x0038	W	0x00000000	Response register 2
SDMMC_RESP3	0x003C	W	0x00000000	Response register 3
SDMMC_MINTSTS	0x0040	W	0x00000000	Masked interrupt status register
SDMMC_RINTSTS	0x0044	W	0x00000000	Raw interrupt status register

Rockchip Confidential

Name	Offset	Size	Reset Value	Description
SDMMC_STATUS	0x0048	W	0x00000106	Status register
SDMMC_FIFOTH	0x004C	W	0x00FF0000	FIFO threshold register
SDMMC_CDETECT	0x0050	W	0x00000001	Card detect register
SDMMC_WRTPRT	0x0054	W	0x00000000	Write protect register
SDMMC_TCBCNT	0x005C	W	0x00000000	Transferred card byte count register
SDMMC_TBBCNT	0x0060	W	0x00000000	Transferred host to FIFO byte count register
SDMMC_DEBNCE	0x0064	W	0x00FFFFFF	Debounce count register
SDMMC_USRID	0x0068	W	0x00000000	User ID register
SDMMC_VERID	0x006C	W	0x5342270A	Version ID register
SDMMC_HCON	0x0070	W	0x04C434C1	Hardware configuration register
SDMMC_UHSREG	0x0074	W	0x00000000	UHS-1 control register
SDMMC_RSTN	0x0078	W	0x00000001	Hardware reset register
SDMMC_BMOD	0x0080	W	0x00000000	Bus mode register
SDMMC_PLDMND	0x0084	W	0x00000000	Poll demand register
SDMMC_DBADDR	0x0088	W	0x00000000	Descriptor list base address register
SDMMC_IDSTS	0x008C	W	0x00000000	Internal DMAC status register
SDMMC_IDINTEN	0x0090	W	0x00000000	Internal DMAC interrupt enable register
SDMMC_DSCADDR	0x0094	W	0x00000000	Current host descriptor address register
SDMMC_BUFADDR	0x0098	W	0x00000000	Current buffer descriptor address register
SDMMC_CARDTHRCTL	0x0100	W	0x00000000	Card threshold control register
SDMMC_BACKEND_POWER	0x0104	W	0x00000000	Back-end power register
SDMMC_EMMCDDR_REG	0x010C	W	0x00000000	eMMC4.5 DDR start bit detection control register
SDMMC_RDYINT_GEN	0x0120	W	0x00FF0000	Card ready interrupt generation control register
SDMMC_CLKGEN_CON0	0x0130	W	0x00000004	Clock generation control register 0
SDMMC_CLKGEN_CON1	0x0134	W	0x00000000	Clock generation control register 1
SDMMC_MISC_CON	0x0138	W	0x00000000	Miscellaneous control register
SDMMC_FIFO_BASE	0x0200	W	0x00000000	FIFO base address register

*Notes:Size:**B**- Byte (8 bits) access, **HW**- Half WORD (16 bits) access, **W**-WORD (32 bits) access, **DW**-Double WORD (64 bits) access*

39.4.2 Detail Register Description

SDMMC_CTRL

Address: Operational Base (0xFF480000) + offset (0x0000)

Bit	Attr	Reset Value	Description
31:26	RO	0x00	reserved
25	RW	0x0	use_internal_dmac Present only for the Internal DMAC configuration; else, it is reserved. 1'b0: The host performs data transfers through the slave interface 1'b1: Internal DMAC used for data transfer
24:12	RO	0x0000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
11	RW	0x0	ceata_device_interrupt_status 1'b0: Interrupts not enabled in CE-ATA device 1'b1: Interrupts are enabled in CE-ATA device Software should appropriately write to this bit after power-on reset or any other reset to CE-ATA device. After reset, usually CE-ATA device interrupt is disabled. If the host enables CE-ATA device interrupt, then software should set this bit.
10	RW	0x0	send_auto_stop_ccsd 1'b0: Clear bit if Host Controller does not reset the bit 1'b1: Send internally generated STOP after sending CCSD to CE-ATA device NOTE: Always set send_auto_stop_ccsd and send_ccsd bits together send_auto_stop_ccsd should not be set independent of send_ccsd. When set, the Host Controller automatically sends internally-generated STOP command (CMD12) to CE-ATA device. After sending internally-generated STOP command, Auto Command Done (ACD) bit in SDMMC_RINTSTS is set and generates interrupt to host if Auto Command Done interrupt is not masked. After sending the CCSD, the Host Controller automatically clears send_auto_stop_ccsd bit.
9	RW	0x0	send_ccsd 1'b0: Clear bit if Host Controller does not reset the bit 1'b1: Send Command Completion Signal Disable (CCSD) to CE-ATA device When set, the Host Controller sends CCSD to CE-ATA device. Software sets this bit only if current command is expecting CCS (that is, RW_BLK) and interrupts are enabled in CE-ATA device. Once the CCSD pattern is sent to device, the Host Controller automatically clears send_ccsd bit. It also sets Command Done (CD) bit in SDMMC_RINTSTS register and generates interrupt to host if Command Done interrupt is not masked. NOTE: Once send_ccsd bit is set, it takes two card clock cycles to drive the CCSD on the CMD line. Due to this, during the boundary conditions it may happen that CCSD is sent to the CE-ATA device, even if the device signalled CCS.
8	RW	0x0	abort_read_data 1'b0: No change 1'b1: After suspend command is issued during read-transfer, software polls card to find when suspend happened. Once suspend occurs, software sets bit to reset data state-machine, which is waiting for next block of data. Bit automatically clears once data state machine resets to idle. Used in SDIO card suspend sequence.
7	RW	0x0	send_irq_response 1'b0: No change 1'b1: Send auto IRQ response Bit automatically clears once response is sent. To wait for MMC card interrupts, software issues CMD40, and the Host Controller waits for interrupt response from MMC card. In meantime, if software wants the Controller to exit waiting for interrupt state, it can set this bit, at which time the Host Controller command state-machine sends CMD40 response on bus and returns to idle state.

Rockchip Confidential

Bit	Attr	Reset Value	Description
6	RW	0x0	read_wait 1'b0: Clear read wait 1'b1: Assert read wait For sending read-wait to SDIO cards.
5	RW	0x0	dma_enable 1'b0: Disable DMA transfer mode 1'b1: Enable DMA transfer mode Even when DMA mode is enabled, host can still push/pop data into or from FIFO; this should not happen during the normal operation. If there is simultaneous FIFO access from host/DMA, the data coherency is lost. Also, there is no arbitration inside the controller to prioritize simultaneous host/DMA access.
4	RW	0x0	int_enable Global interrupt enable/disable bit 1'b0: Disable interrupts 1'b1: Enable interrupts The int port is 1 only when this bit is 1 and one or more unmasked interrupts are set.
3	RO	0x0	reserved
2	W1C	0x0	dma_reset 1'b0: No change 1'b1: Reset internal DMA interface control logic To reset DMA interface, firmware should set bit to 1. This bit is auto-cleared after two AHB clocks.
1	W1C	0x0	fifo_reset 1'b0: No change 1'b1: Reset to data FIFO to reset FIFO pointers To reset FIFO, firmware should set bit to 1. This bit is auto-cleared after completion of reset operation.
0	W1C	0x0	controller_reset 1'b0: No change 1'b1: Reset Host Controller To reset Host Controller, firmware should set bit to 1. This bit is auto-cleared after two AHB and two cclk_in clock cycles. This resets: a. BIU/CIU interface b. CIU and state machines c. abort_read_data, send_irq_response, and read_wait bits of SDMMC_CTRL register d. start_cmd bit of SDMMC_CMD register Does not affect any registers or DMA interface, or FIFO or controller interrupts.

SDMMC_PWREN

Address: Operational Base (0xFF480000) + offset (0x0004)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	power_enable Power on/off switch for the card. Once power is turned on, firmware should wait for regulator/switch ramp-up time before trying to initialize card. 1'b0: Power off 1'b1: Power on Bit values output to card_power_en port.

SDMMC_CLKDIV

Rockchip Confidential

Address: Operational Base (0xFF480000) + offset (0x0008)

Bit	Attr	Reset Value	Description
31:8	RO	0x000000	reserved
7:0	RW	0x00	clk_divider0 Clock divider-0 value. Clock division is 2*n. For example, value of 0 means divide by 2*0 = 0 (no division, bypass), value of 1 means divide by 2*1 = 2, and so on. The recommended value is 0 or 1.

SDMMC_CLKSRC

Address: Operational Base (0xFF480000) + offset (0x000C)

Bit	Attr	Reset Value	Description
31:2	RO	0x00000000	reserved
1:0	RW	0x0	clk_source Clock divider source. 2'b00: Clock divider 0 The cclk_out is always from clock divider 0, and this register is not implemented.

SDMMC_CLKENA

Address: Operational Base (0xFF480000) + offset (0x0010)

Bit	Attr	Reset Value	Description
31:17	RO	0x0000	reserved
16	RW	0x0	cclk_low_power Low-power control for SD card clock and MMC card clock supported. 1'b0: Non-low-power mode 1'b1: Low-power mode. Stop clock when card in IDLE (should be normally set to only MMC and SD memory cards; for SDIO cards, if interrupts must be detected, clock should not be stopped).
15:1	RO	0x0000	reserved
0	RW	0x0	cclk_enable Clock-enable control for SD card clock and MMC card clock supported. 1'b0: Clock disabled 1'b1: Clock enabled

SDMMC_TMOUT

Address: Operational Base (0xFF480000) + offset (0x0014)

Bit	Attr	Reset Value	Description
31:8	RW	0xffffff	data_timeout Value for card data read timeout; same value also used for data starvation by host timeout. Value is in number of card output clock. Note: The software timer should be used if the timeout value is in the order of 100 ms. In this case, read data timeout interrupt needs to be disabled.
7:0	RW	0x40	response_timeout Response timeout value. Value is in number of card output clock cclk_out.

SDMMC_CTYPE

Address: Operational Base (0xFF480000) + offset (0x0018)

Bit	Attr	Reset Value	Description
31:17	RO	0x0000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
16	RW	0x0	card_width_8 Indicates if card is 8-bit. 1'b0: Non 8-bit mode 1'b1: 8-bit mode
15:1	RO	0x0000	reserved
0	RW	0x0	card_width Indicates if card is 1-bit or 4-bit. 1'b0: 1-bit mode 1'b1: 4-bit mode

SDMMC_BLKSIZ

Address: Operational Base (0xFF480000) + offset (0x001C)

Bit	Attr	Reset Value	Description
31:16	RO	0x0000	reserved
15:0	RW	0x0200	block_size Block size

SDMMC_BYTCNT

Address: Operational Base (0xFF480000) + offset (0x0020)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000200	byte_count Number of bytes to be transferred; should be integer multiple of block size for block transfers. For undefined number of byte transfers, byte count should be set to 0. When byte count is set to 0, it is responsibility of host to explicitly send stop/abort command to terminate data transfer.

SDMMC_INTMASK

Address: Operational Base (0xFF480000) + offset (0x0024)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved
24	RW	0x0	sdio_int_mask 1'b0: SDIO interrupt not masked 1'b1: SDIO interrupt masked
23:17	RO	0x00	reserved
16	RW	0x0	data_nobusy_int_mask 1'b0: Data no busy interrupt not masked 1'b1: Data no busy interrupt masked

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RW	0x0000	int_mask Bits used to mask unwanted interrupts. Value of 0 masks interrupt; value of 1 enables interrupt. bit 15: End-bit error (read)/Write no CRC (EBE) bit 14: Auto command done (ACD) bit 13: Start-bit error (SBE) bit 12: Hardware locked write error (HLE) bit 11: FIFO underrun/overrun error (FRUN) bit 10: Data starvation-by-host timeout (HTO) /Volt_switch_int bit 9: Data read timeout (DRTO) bit 8: Response timeout (RTO) bit 7: Data CRC error (DCRC) bit 6: Response CRC error (RCRC) bit 5: Receive FIFO data request (RXDR) bit 4: Transmit FIFO data request (TXDR) bit 3: Data transfer over (DTO) bit 2: Command done (CD) bit 1: Response error (RE) bit 0: Card detect (CD)

SDMMC_CMDARG

Address: Operational Base (0xFF480000) + offset (0x0028)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	cmd_arg Value indicates command argument to be passed to card

SDMMC_CMD

Address: Operational Base (0xFF480000) + offset (0x002C)

Bit	Attr	Reset Value	Description
31	RW	0x0	start_cmd Start command. Once command is taken by CIU, bit is cleared. When bit is set, host should not attempt to write to any command registers. If write is attempted, hardware lock error is set in raw interrupt register. Once command is sent and response is received from SD/MMC cards, Command Done bit is set in raw interrupt register.
30	RO	0x0	reserved
29	RW	0x1	use_hold_reg Use hold register. 1'b0: CMD and DATA sent to card bypassing hold register 1'b1: CMD and DATA sent to card through the hold register
28	RW	0x0	volt_switch Voltage switch bit. 1'b0: No voltage switching 1'b1: Voltage switching enabled; must be set for CMD11 only.
27	RW	0x0	boot_mode Boot mode selection. 1'b0: Mandatory boot operation 1'b1: Alternate boot operation
26	RW	0x0	disable_boot Disable boot. When software sets this bit along with start_cmd, CIU terminates the boot operation. Do not set disable_boot and enable_boot together.

Rockchip Confidential

Bit	Attr	Reset Value	Description
25	RW	0x0	expect_boot_ack Expect boot acknowledge. When software sets this bit along with enable_boot, CIU expects a boot acknowledge start pattern of 0-1-0 from the selected card.
24	RW	0x0	enable_boot Enable boot. This bit should be set only for mandatory boot mode. When Software sets this bit along with start_cmd, CIU starts the boot sequence for the corresponding card by asserting the CMD line low. Do not set disable_boot and enable_boot together.
23	RW	0x0	ccs_expected 1'b0: Interrupts are not enabled in CE-ATA device or command does not expect CCS from device 1'b1: Interrupts are enabled in CE-ATA device and RW_BLK command expects command completion signal from CE-ATA device If the command expects command completion signal (CCS) from the CE-ATA device, the software should set this control bit. The Host Controller sets data transfer over (DTO) bit in SDMMC_RINTSTS register and generates interrupt to host if data transfer over interrupt is not masked.
22	RW	0x0	read_ceata_device 1'b0: Host is not performing read access towards CE-ATA device 1'b1: Host is performing read access towards CE-ATA device Software should set this bit to indicate that CE-ATA device is being accessed for read transfer. This bit is used to disable read data timeout indication while performing CE-ATA read transfers. Maximum value of I/O transmission delay can be no less than 10 seconds. The Host Controller should not indicate read data timeout while waiting for data from CE-ATA device.
21	RW	0x0	update_clock_regs_only 1'b0: Normal command sequence 1'b1: Do not send commands, just update clock register value into card clock domain. Following register values transferred into card clock domain: SDMMC_CLKDIV, SDMMC_CLRSRC, SDMMC_CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards. During normal command sequence, when update_clock_regs_only = 0, following control registers are transferred from BIU to CIU: SDMMC_CMD, SDMMC_CMDARG, SDMMC_TMOUT, SDMMC_CTYPE, SDMMC_BLKSIZ, SDMMC_BYTCNT. CIU uses new register values for new command sequence to card. When bit is set, there are no Command Done interrupts because no command is sent to SD_MMC_CEATA cards.
20:16	RO	0x00	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
15	RW	0x0	send_initialization 1'b0: Do not send initialization sequence (80 clocks of 1) before sending this command 1'b1: Send initialization sequence before sending this command After power on, 80 clocks must be sent to card for initialization before sending any commands to card. Bit should be set while sending first command to card so that controller will initialize clocks before sending command to card. This bit should not be set for either of the boot modes (alternate or mandatory).
14	RW	0x0	stop_abort_cmd 1'b0: Neither stop nor abort command to stop current data transfer in progress. If abort is sent to function-number currently selected or not in data-transfer mode, then bit should be set to 0. 1'b1: Stop or abort command intended to stop current data transfer in progress. When open-ended or predefined data transfer is in progress, and host issues stop or abort command to stop data transfer, bit should be set so that command/data state-machines of CIU can return correctly to idle state. This is also applicable for Boot mode transfers. To Abort boot mode, this bit should be set along with SDMMC_CMD[26]=disable_boot.
13	RW	0x0	wait_prvdata_complete 1'b0: Send command at once, even if previous data transfer has not completed 1'b1: Wait for previous data transfer completion before sending command The wait_prvdata_complete=0 option typically used to query status of card during data transfer or to stop current data transfer; card_number should be same as in previous command.
12	RW	0x0	send_auto_stop 1'b0: No stop command sent at end of data transfer 1'b1: Send stop command at end of data transfer When set, the Host Controller sends stop command to card at end of data transfer. a. When send_auto_stop bit should be set, since some data transfers do not need explicit stop commands b. Open-ended transfers that software should explicitly send to stop command Additionally, when "resume" is sent to resume-suspended memory access of SD-Combo card, bit should be set correctly if suspended data transfer needs send_auto_stop. Don't care if no data expected from card.
11	RW	0x0	transfer_mode 1'b0: Block data transfer command 1'b1: Stream data transfer command Don't care if no data expected.
10	RW	0x0	wr 1'b0: Read from card 1'b1: Write to card Don't care if no data expected from card.
9	RW	0x0	data_expected 1'b0: No data transfer expected (read/write) 1'b1: Data transfer expected (read/write)

Rockchip Confidential

Bit	Attr	Reset Value	Description
8	RW	0x0	check_response_crc 1'b0: Do not check response CRC 1'b1: Check response CRC Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller.
7	RW	0x0	response_length 1'b0: Short response expected from card 1'b1: Long response expected from card
6	RW	0x0	response_expect 1'b0: No response expected from card 1'b1: Response expected from card
5:0	RW	0x00	cmd_index Command index

SDMMC_RESP0

Address: Operational Base (0xFF480000) + offset (0x0030)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	response0 Bit[31:0] of response

SDMMC_RESP1

Address: Operational Base (0xFF480000) + offset (0x0034)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	response1 Register represents bit[63:32] of long response. When CIU sends auto-stop command, then response is saved in register. Response for previous command sent by host is still preserved in response 0 register. Additional auto-stop issued only for data transfer commands, and response type is always "short" for them.

SDMMC_RESP2

Address: **Operational Base (0xFF480000)** + offset (0x0038)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	response2 Bit[95:64] of long response

SDMMC_RESP3

Address: **Operational Base (0xFF480000)** + offset (0x003C)

Bit	Attr	Reset Value	Description
31:0	RO	0x00000000	response3 Bit[127:96] of long response

SDMMC_MINTSTS

Address: Operational Base (0xFF480000) + offset (0x0040)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved
24	RO	0x0	sdio_interrupt SDIO interrupt status when sdio_int_mask is set
23:17	RO	0x00	reserved
16	RW	0x0	data_nobusy_int_status Data no busy interrupt status when data_nobusy_int_mask is set

Rockchip Confidential

Bit	Attr	Reset Value	Description
15:0	RO	0x0000	int_status Interrupt enabled only if corresponding bit in interrupt mask register is set. bit 15: End-bit error (read)/Write no CRC (EBE) bit 14: Auto command done (ACD) bit 13: Start-bit error (SBE) bit 12: Hardware locked write error (HLE) bit 11: FIFO underrun/overrun error (FRUN) bit 10: Data starvation-by-host timeout (HTO) /Volt_switch_int bit 9: Data read timeout (DRTO) bit 8: Response timeout (RTO) bit 7: Data CRC error (DCRC) bit 6: Response CRC error (RCRC) bit 5: Receive FIFO data request (RXDR) bit 4: Transmit FIFO data request (TXDR) bit 3: Data transfer over (DTO) bit 2: Command done (CD) bit 1: Response error (RE) bit 0: Card detect (CD)

SDMMC_RINTSTS

Address: Operational Base (0xFF480000) + offset (0x0044)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved
24	R/WSC	0x0	sdio_interrupt Raw SDIO interrupt status. Write value of 1 clears this bit, and value of 0 leaves bit intact.
23:17	RO	0x00	reserved
16	R/WSC	0x0	data_nobusy_int_status Raw data no busy interrupt status. Write value of 1 clears this bit, and value of 0 leaves bit intact.
15:0	R/WSC	0x0000	int_status Raw interrupt status. Writes to bits clear status bit. Write value of 1 clears status bit, and value of 0 leaves bit intact. bit 15: End-bit error (read)/Write no CRC (EBE) bit 14: Auto command done (ACD) bit 13: Start-bit error (SBE) bit 12: Hardware locked write error (HLE) bit 11: FIFO underrun/overrun error (FRUN) bit 10: Data starvation-by-host timeout (HTO) /Volt_switch_int bit 9: Data read timeout (DRTO) bit 8: Response timeout (RTO) bit 7: Data CRC error (DCRC) bit 6: Response CRC error (RCRC) bit 5: Receive FIFO data request (RXDR) bit 4: Transmit FIFO data request (TXDR) bit 3: Data transfer over (DTO) bit 2: Command done (CD) bit 1: Response error (RE) bit 0: Card detect (CD)

SDMMC_STATUS

Address: Operational Base (0xFF480000) + offset (0x0048)

Rockchip Confidential

Bit	Attr	Reset Value	Description
31	RO	0x0	dma_req DMA request signal state
30	RO	0x0	dma_ack DMA acknowledge signal state
29:17	RO	0x0000	fifo_count Number of filled locations in FIFO
16:11	RO	0x00	response_index Index of previous response, including any auto-stop sent by core.
10	RO	0x0	data_state_mc_busy Data transmit or receive state-machine is busy
9	RO	0x0	data_busy Inverted version of raw selected card_data[0]. 1'b0: Card data not busy 1'b1: Card data busy
8	RO	0x1	data_3_status Raw selected card_data[3]; checks whether card is present. 1'b0: Card not present 1'b1: Card present
7:4	RO	0x0	command_fsm_states Command FSM states: 4'h0: Idle 4'h1: Send init sequence 4'h2: Tx cmd start bit 4'h3: Tx cmd tx bit 4'h4: Tx cmd index + arg 4'h5: Tx cmd crc7 4'h6: Tx cmd end bit 4'h7: Tx resp start bit 4'h8: Rx resp IRQ response 4'h9: Rx resp tx bit 4'ha: Rx resp cmd idx 4'hb: Rx resp data 4'hc: Rx resp crc7 4'hd: Rx resp end bit 4'he: Cmd path wait NCC 4'hf: Wait CMD-to-response turnaround The command FSM state is represented using 19 bits. The SDMMC_STATUS register[7:4] has 4 bits to represent the command FSM states. Using these 4 bits, only 16 states can be represented. Thus three states cannot be represented in the SDMMC_STATUS[7:4] register. The three states that are not represented in the SDMMC_STATUS register[7:4] are: Bit 16: Wait for CCS Bit 17: Send CCSD Bit 18: Boot Mode Due to this, while command FSM is in "Wait for CCS state" or "Send CCSD" or "Boot Mode", the SDMMC_STATUS register indicates status as 0 for the bit field [7:4].
3	RO	0x0	fifo_full FIFO is full status
2	RO	0x1	fifo_empty FIFO is empty status
1	RO	0x1	fifo_tx_watermark FIFO reached Transmit watermark level; not qualified with data transfer.

Rockchip Confidential

Bit	Attr	Reset Value	Description
0	RO	0x0	fifo_rx_watermark FIFO reached Receive watermark level; not qualified with data transfer.

SDMMC_FIFOTH

Address: Operational Base (0xFF480000) + offset (0x004C)

Bit	Attr	Reset Value	Description
31	RO	0x0	reserved
30:28	RW	0x0	dma_mutiple_transaction_size Burst size of multiple transaction; should be programmed same as DMA controller multiple-transaction-size SRC/DEST_MSIZE. 3'b000: 1 transfers 3'b001: 4 transfers 3'b010: 8 transfers 3'b011: 16 transfers 3'b100: 32 transfers 3'b101: 64 transfers 3'b110: 128 transfers 3'b111: 256 transfers The unit for transfer is 32bits.
27:16	RW	0x0ff	rx_wmark FIFO threshold watermark level when receiving data to card. When FIFO data count reaches greater than this number, DMA/FIFO request is raised. During end of packet, request is generated regardless of threshold programming in order to complete any remaining data. In non-DMA mode, when receiver FIFO threshold (RXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, interrupt is not generated if threshold programming is larger than any remaining data. It is responsibility of host to read remaining bytes on seeing Data Transfer Done interrupt. In DMA mode, at end of packet, even if remaining bytes are less than threshold, DMA request does single transfers to flush out any remaining bytes before Data Transfer Done interrupt is set. 12 bits-1 bit less than FIFO-count of status register, which is 13 bits. Limitation: rx_wmark <= FIFO_DEPTH-2 Recommended: (FIFO_DEPTH/2) - 1; (means greater than (FIFO_DEPTH/2) - 1) NOTE: In DMA mode during CCS time-out, the DMA does not generate the request at the end of packet, even if remaining bytes are less than threshold. In this case, there will be some data left in the FIFO. It is the responsibility of the application to reset the FIFO after the CCS timeout.
15:12	RO	0x0	reserved
11:0	RW	0x000	tx_wmark FIFO threshold watermark level when transmitting data to card. When FIFO data count is less than or equal to this number, DMA/FIFO request is raised. If Interrupt is enabled, then interrupt occurs. During end of packet, request or interrupt is generated, regardless of threshold programming. In non-DMA mode, when transmit FIFO threshold (TXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, on last interrupt, host is responsible for filling FIFO with only required remaining bytes

Rockchip Confidential

Bit	Attr	Reset Value	Description
			(not before FIFO is full or after CIU completes data transfers, because FIFO may not be empty). In DMA mode, at end of packet, if last transfer is less than burst size, DMA controller does single cycles until required bytes are transferred. 12 bits -1 bit less than FIFO-count of status register, which is 13 bits. Limitation: tx_wmark >= 1; Recommended: FIFO_DEPTH/2; (means less than or equal to FIFO_DEPTH/2)

SDMMC_CDETECT

Rockchip Confidential

Bit	Attr	Reset Value	Description
31:17	RO	0x0000	reserved
16	RW	0x0	ddr_reg DDR mode. These bits indicate DDR mode of operation to the core for the data transfer. 1'b0: Non-DDR mode 1'b1: DDR mode
15:0	RO	0x0000	reserved

SDMMC_RSTN

Address: Operational Base (0xFF480000) + offset (0x0078)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x1	card_reset Hardware reset. 1'b0: Active mode 1'b1: Reset These bits cause the cards to enter pre-idle state, which requires them to be re-initialized.

SDMMC_BMOD

Address: Operational Base (0xFF480000) + offset (0x0080)

Bit	Attr	Reset Value	Description
31:11	RO	0x000000	reserved
10:8	RO	0x0	pbl Programmable burst length. These bits indicate the maximum number of beats to be performed in one IDMAC transaction. The IDMAC will always attempt to burst as specified in PBL each time it starts a Burst transfer on the host bus. The permissible values are 1, 4, 8, 16, 32, 64, 128 and 256. This value is the mirror of MSIZE of SDMMC_FIFOTH register. In order to change this value, write the required value to SDMMC_FIFOTH register. This is an encode value as follows. 3'b000: 1 transfers 3'b001: 4 transfers 3'b010: 8 transfers 3'b011: 16 transfers 3'b100: 32 transfers 3'b101: 64 transfers 3'b110: 128 transfers 3'b111: 256 transfers Transfer unit is 32 bits. PBL is a read-only value and is applicable only for data access; it does not apply to descriptor accesses.
7	RW	0x0	de IDMAC enable. When set, the IDMAC is enabled.
6:2	RW	0x00	dsl Descriptor skip length. Specifies the number of word to skip between two unchained descriptors. This is applicable only for dual buffer structure.

Rockchip Confidential

Bit	Attr	Reset Value	Description
1	RW	0x0	fb Fixed burst. Controls whether the AHB Master interface performs fixed burst transfers or not. When set, the AHB will use only SINGLE, INCR4, INCR8 or INCR16 during start of normal burst transfers. When reset, the AHB will use SINGLE and INCR burst transfer operations.
0	RW	0x0	swr Software reset. When set, the DMA Controller resets all its internal registers. It is automatically cleared after 1 clock cycle.

SDMMC_PLDMND

Address: Operational Base (0xFF480000) + offset (0x0084)

Bit	Attr	Reset Value	Description
31:0	WO	0x00000000	pd Poll demand. If the OWN bit of a descriptor is not set, the FSM goes to the suspend state. The host needs to write any value into this register for the IDMAC FSM to resume normal descriptor fetch operation.

SDMMC_DBADDR

Address: Operational Base (0xFF480000) + offset (0x0088)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	sbl Start of descriptor list. Contains the base address of the first descriptor. The LSB bits[1:0] are ignored and taken as all-zero by the IDMAC internally. Hence these LSB bits are read-only.

SDMMC_IDSTS

Address: Operational Base (0xFF480000) + offset (0x008C)

Bit	Attr	Reset Value	Description
31:17	RO	0x0000	reserved
16:13	RO	0x0	fsm DMAC FSM present state. 4'h0: DMA_IDLE 4'h1: DMA_SUSPEND 4'h2: DESC_RD 4'h3: DESC_CHK 4'h4: DMA_RD_REQ_WAI 4'h5: DMA_WR_REQ_WAI 4'h6: DMA_RD 4'h7: DMA_WR 4'h8: DESC_CLOSE Others: Reserved
12:10	RO	0x0	eb Error bits. Indicates the type of error that caused a bus error. Valid only with fatal bus. 3'h1: Host abort received during transmission 3'h2: Host abort received during reception Others: Reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
9	RW	0x0	ais Abnormal interrupt summary. Logical OR of the following: SDMMC_IDSTS[2] fatal bus interrupt SDMMC_IDSTS[4] du bit interrupt Only unmasked bits affect this bit. This is a sticky bit and must be cleared each time a corresponding bit that causes ais to be set is cleared. Writing a 1 clears this bit.
8	RW	0x0	nis Normal interrupt summary. Logical OR of the following: SDMMC_IDSTS[0] transmit interrupt SDMMC_IDSTS[1] receive interrupt Only unmasked bits affect this bit. This is a sticky bit and must be cleared each time a corresponding bit that causes nis to be set is cleared. Writing a 1 clears this bit.
7:6	RO	0x0	reserved
5	RW	0x0	ces Card error summary. Indicates the status of the transaction to/from the card; also present in SDMMC_RINTSTS. Indicates the logical OR of the following bits: EBE: End Bit Error RTO: Response Timeout/Boot Ack Timeout RCRC: Response CRC SBE: Start Bit Error DRTO: Data Read Timeout/BDS timeout DCRC: Data CRC for Receive RE: Response Error Writing a 1 clears this bit. The abort condition of the IDMAC depends on the setting of this CES bit. If the CES bit is enabled, then the IDMAC aborts on a "response error"; however, it will not abort if the CES bit is cleared.
4	RW	0x0	dui Descriptor unavailable interrupt. This bit is set when the descriptor is unavailable due to OWN bit = 0 (DES0[31] =0). Writing a 1 clears this bit.
3	RO	0x0	reserved
2	RW	0x0	fbe Fatal bus error interrupt. Indicates that a bus error occurred (SDMMC_IDSTS[12:10]). When this bit is set, the DMA disables all its bus accesses. Writing a 1 clears this bit.
1	RW	0x0	ri Receive interrupt. Indicates the completion of data reception for a descriptor. Writing a 1 clears this bit.
0	RW	0x0	ti Transmit interrupt. Indicates that data transmission is finished for a descriptor. Writing 1 clears this bit.

SDMMC_IDINTEN

Address: Operational Base (0xFF480000) + offset (0x0090)

Bit	Attr	Reset Value	Description
31:10	RO	0x000000	reserved

Rockchip Confidential

Bit	Attr	Reset Value	Description
9	RW	0x0	ai Abnormal interrupt summary enable. When set, an abnormal interrupt is enabled. This bit enables the following bits: SDMMC_IDINTEN[2] fatal bus error interrupt SDMMC_IDINTEN[4] du interrupt
8	RW	0x0	ni Normal interrupt summary enable. When set, a normal interrupt is enabled. When reset, a normal interrupt is disabled. This bit enables the following bits: SDMMC_IDINTEN[0] transmit interrupt SDMMC_IDINTEN[1] receive interrupt
7:6	RO	0x0	reserved
5	RW	0x0	ces Card error summary interrupt enable. When set, it enables the card interrupt summary.
4	RW	0x0	du Descriptor unavailable interrupt. When set along with abnormal interrupt summary enable, the du interrupt is enabled.
3	RO	0x0	reserved
2	RW	0x0	fbe Fatal bus error enable. When set with abnormal interrupt summary enable, the fatal bus error interrupt is enabled. When reset, fatal bus error enable interrupt is disabled.
1	RW	0x0	ri Receive interrupt enable. When set with normal interrupt summary enable, receive interrupt is enabled. When reset, receive interrupt is disabled.
0	RW	0x0	ti Transmit interrupt enable. When set with normal interrupt summary enable, transmit interrupt is enabled. When reset, transmit interrupt is disabled.

SDMMC_DSCADDR

Address: Operational Base (0xFF480000) + offset (0x0094)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	hda Host descriptor address pointer. This register points to the start address of the current descriptor read by the IDMAC. Cleared on reset. Pointer updated by IDMAC during operation.

SDMMC_BUFADDR

Address: Operational Base (0xFF480000) + offset (0x0098)

Bit	Attr	Reset Value	Description
31:0	RW	0x00000000	hba Host buffer address pointer. This register points to the current data buffer address being accessed by the IDMAC. Cleared on Reset. Pointer updated by IDMAC during operation.

Rockchip Confidential

SDMMC_CARDTHRCTL

Address: Operational Base (0xFF480000) + offset (0x0100)

Bit	Attr	Reset Value	Description
31:28	RO	0x0	reserved
27:16	RW	0x000	card_rd_thres Card read threshold size
15:2	RO	0x0000	reserved
1	RW	0x0	busy_clr_int_en Busy clear interrupt. 1'b0: Busy clear interrupt disabled 1'b1: Busy clear interrupt enabled Note: The application can disable this feature if it does not want to wait for a busy clear interrupt. For example, in a multi-card scenario, the application can switch to the other card without waiting for a busy to be completed. In such cases, the application can use the polling method to determine the status of busy. By default this feature is disabled and backward-compatible to the legacy drivers where polling is used.
0	RW	0x0	card_rd_thres_en Card read threshold enable. 1'b0: Card read threshold disabled 1'b1: Card read threshold enabled. The host initiates read transfer only if card_rd_thres amount of space is available in receive FIFO.

SDMMC_BACKEND_POWER

Address: Operational Base (0xFF480000) + offset (0x0104)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	back_end_power Back end power. 1'b0: Off; Reset 1'b1: Back-end power supplied to card application

SDMMC_EMMCDDR_REG

Address: Operational Base (0xFF480000) + offset (0x010C)

Bit	Attr	Reset Value	Description
31:1	RO	0x00000000	reserved
0	RW	0x0	half_start_bit Control for start bit detection mechanism inside Host Controller based on duration of start bit. For eMMC 4.5, start bit can be: 1'b0: Full cycle (half_start_bit=0) 1'b1: Less than one full cycle (half_start_bit=1) Set half_start_bit=1 for eMMC 4.5 and above; set to 0 for SD applications.

SDMMC_RDYINT_GEN

Address: Operational Base (0xFF480000) + offset (0x0120)

Bit	Attr	Reset Value	Description
31:25	RO	0x00	reserved
24	RO	0x0	rdyint_cnt_finish Counter finish indication. When high, it indicates that the rdyint counter is finished.

Rockchip Confidential

Bit	Attr	Reset Value	Description
23:16	RO	0xff	rdyint_cnt_status Couner status, reflect internal counter value.
15:9	RO	0x00	reserved
8	RW	0x0	rdyint_gen_working Working indication for rdyint generator. When high, Host Controller start to count and generate one rdyint trigger. After the rdyint trigger is generated, this bit will be set to 0 by Host Controller. So software should set it to 1 before detecting next interrupt.
7:0	RW	0x00	rdyint_gen_maxval Max counter value to detect cdata_in0 high value for generating rdyint, based on internal clock frequency.

SDMMC_CLKGEN_CON0

Address: Operational Base (0xFF480000) + offset (0x0130)

Bit	Attr	Reset Value	Description

39.6 Application Notes

39.6.1 Software/Hardware Restriction

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.

To avoid glitches in the card clock outputs, the software should use the following steps when changing the card clock frequency:

1) Before disable the clocks, ensure that the card is not busy due to any previous data command. To determine this, check for 0 in bit9 of SDMMC_STATUS register.
2) Update the Clock Enable register to disable clock. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting:

- start_cmd bit
- "update clock registers only" bits
- "wait_previous data complete" bit

  Wait for the CIU to take the command by polling for 0 on the start_cmd bit.

3) Set the start_cmd bit to update the Clock Divider and/or Clock Source register, and send a command to the CIU in order to update the clock registers; wait for the CIU to take the command.
4) Set start_cmd to update the Clock Enable register in order to enable the required clocks and send a command to the CIU to update the clock registers; wait for the CIU to take the command.

In non-DMA mode, while reading from a card, the Data Transfer Over (SDMMC_RINTSTS[3]) interrupt occurs as soon as the data transfer from the card is over. There still could be some data left in the FIFO, and the RX_WMark interrupt may or may not occur, depending on the remaining bytes in the FIFO. Software should read any remaining bytes upon seeing the Data Transfer Over (DTO) interrupt. While using the external DMA interface for reading from a card, the DTO interrupt occurs only after all the data is flushed to memory by the DMA interface unit.

While writing to a card in external DMA mode, if an undefined-length transfer is selected by setting the Byte Count Register to 0, the DMA logic will likely request more data than it will send to the card, since it has no way of knowing at which point the software will stop the transfer. The DMA request stops as soon as the DTO is set by the CIU.

If the software issues a controller_reset command by setting control register bit[0] to 1, all the CIU state machines are reset; the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued, then:

- Any pending DMA transfer on the bus completes correctly
- DMA data read is ignored
- Write data is unknown(x)

Additionally, if dma_reset is also issued, any pending DMA transfer is abruptly terminated. When the DMA is used, the DMA controller channel should also be reset and reprogrammed.

If any of the previous data commands do not properly terminate, then the software should issue the FIFO reset in order to remove any residual data, if any, in the FIFO. After asserting the FIFO reset, you should wait until this bit is cleared.

One data-transfer requirement between the FIFO and host is that the number of transfers should be a multiple of the FIFO data width (32bits). For example, you want to write only

Rockchip Confidential

15 bytes to an SD/MMC card (SDMMC_BYTCNT), the host should write 16 bytes to the FIFO or program the DMA to do 16-byte transfers. The software can still program the Byte Count register to only 15, at which point only 15 bytes will be transferred to the card. Similarly, when 15 bytes are read from a card, the host should still read all 16 bytes from the FIFO. It is recommended that you not change the FIFO threshold register in the middle of data transfers.

39.6.2 Programming Sequence

39.6.2.1 Initialization

Following figure illustrates the initialization flow.

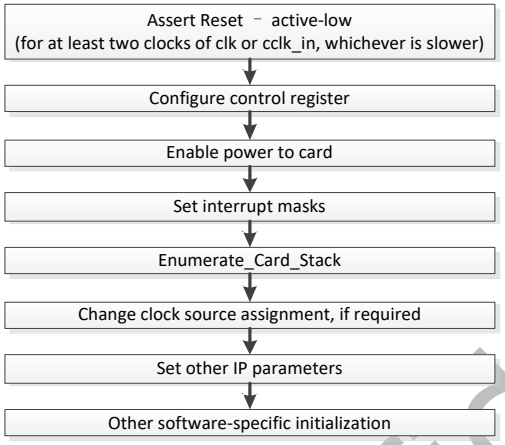

Fig. 39-9 Host Controller Initialization Sequence

Once the power and clocks are stable, reset_n should be asserted(active-low) for at least two cycles of clk or cclk_in, whichever is slower. The reset initializes the registers, ports, FIFO-pointers, DMA interface controls, and state-machines in the design. After power-on reset, the software should do the following:

1) Configure control register – For MMC mode, enable the open-drain pullup by setting enable_OD_pullup(bit24) in the SDMMC_CTRL register.
2) Enable power to cards – Before enabling the power, confirm that the voltage setting to the voltage regulators is correct. Enable power to the connected cards by setting the corresponding bit to 1 in the Power Enable register. Wait for the power ramp-up time.
3) Set masks for interrupts by clearing appropriate bits in the Interrupt Mask register. Set the global int_enable bit of the SDMMC_CTRL register. It is recommended that you write 0xffff_ffff to the Raw Interrupt register in order to clear any pending interrupts before setting the int_enable bit.
4) Enumerate card stack – Each card is enumerated according to card type; for details, refer to "Enumerated Card Stack". For enumeration, you should restrict the clock frequency to 400KHz.
5) Changing clock source assignment – set the card frequency using the clock-divider and clock-source registers; for details, refer to "Clock Programming". MMC cards operate at a maximum of 20MHz (at maximum of 52MHz in high-speed mode). SD mode operates at a maximum of 25MHz (at maximum of 50MHz in high-speed mode).
6) Set other parameters, which normally do not need to be changed with every command, with a typical value such as timeout values in cclk_out according to SD/MMC specifications.

- ResponseTimeOut = 0x64
- DataTimeOut = highest of one of the following:
- (10*((TAAC*Fop)+(100*NSAC))
- Host FIFO read/write latency from FIFO empty/full
- Set the debounce value to 25ms(default:0x0fffff) in host clock cycle units in the SDMMC_DEBNCE register.

FIFO threshold value in bytes in the SDMMC_FIFOTH register.

39.6.2.2 Enumerated Card Stack

The card stack does the following:

- Enumerates all connected cards
- Sets the RCA for the connected cards

Rockchip Confidential

- Reads card-specific information
- Stores card-specific information locally

Enumeration depends on the operating mode of the SD/MMC card; the card type is first identified and the appropriate card enumeration routine is called.

1) Check if the card is connected.
2) Clear the card type register to set the card width as a single bit. For the given card number, clear the corresponding bits in the card_type register. Clear the register bit for a 1-bit, 4-bit bus width. For example, for card number=1, clear bit 0 and bit 16 of the card_type register.
3) Set clock frequency to FOD=400KHz, maximum – Program clock divider0 (bits 0-7 in the SDMMC_CLKDIV register) value to one-half of the cclk_in frequency divided by 400KHz. For example, if cclk_in is 20MHz, then the value is 20, 000/(2*400)=25.
4) Identify the card type; that is, SD, MMC, or SDIO.
   a. Send CMD5 first. If a response is received, then the card is SDIO
   b. If not, send CMD8 with the following Argument
      Bit[31:12] = 20'h0 //reserved bits
      Bit[11:8] = 4'b0001 //VHS value
      Bit[7:0] = 8'b10101010 //Preferred Check Pattern by SD2.0
   c. If Response is received the card supports High Capacity SD2.0 then send ACMD41 with the following Argument
      Bit[31] = 1'b0; //Reserved bits
      Bit[30] = 1'b1; //High Capacity Status
      Bit[29:24] = 6'h0; //Reserved bits
      Bit[23:0] = Supported Voltage Range
   d. If Response is received for ACMD41 then the card is SD. Otherwise the card is MMC.
   e. If response is not received for initial CMD8 then card does not support High Capacity SD2.0, then issue CMD0 followed by ACMD41 with the following Argument
      Bit[31] = 1'b0; //Reserved bits
      Bit[30] = 1'b0; //High Capacity Status
      Bit[29:24] = 6'h0; //Reserved bits
      Bit[23:0] = Supported Voltage Range
5) Enumerate the card according to the card type.
6) Use a clock source with a frequency = Fod (that is, 400KHz) and use the following enumeration command sequence:

- SD card – Send CMD0, CMD8, ACMD41, CMD2, CMD3.
- MMC – Send CMD0, CMD1, CMD2, CMD3.

39.6.2.3 Clock Programming

The Host Controller supports one clock source. The clock to an individual card can be enabled or disabled. Registers that support this are:

- SDMMC_CLKDIV – Programs individual clock source frequency. SDMMC_CLKDIV limited to 0 or 1 is recommended.
- SDMMC_CLKSRC – Assign clock source for each card.
- SDMMC_CLKENA – Enables or disables clock for individual card and enables low-power mode, which automatically stops the clock to a card when the card is idle for more than 8 clocks.

The Host Controller loads each of these registers only when the start_cmd bit and the update_clk_regs_only bit in the SDMMC_CMD register are set. When a command is successfully loaded, the Host Controller clears this bit, unless the Host Controller already has another command in the queue, at which point it gives an HLE(Hardware Locked Error). Software should look for the start_cmd and the update_clk_regs_only bits, and should also set the wait_prvdata_complete bit to ensure that clock parameters do not change during data transfer. Note that even though start_cmd is set for updating clock registers, the Host Controller does not raise a command_done signal upon command completion.

The following shows how to program these registers:

1) Confirm that no card is engaged in any transaction; if there is a transaction, wait until it finishes.
2) Stop all clocks by writing 0 to the SDMMC_CLKENA register. Set the start_cmd,

Rockchip Confidential

Update_clk_regs_only, and wait_prvdata_complete bits in the SDMMC_CMD register. Wait until start_cmd is cleared or an HLE is set; in case of an HLE, repeat the command.

3) Program the SDMMC_CLKDIV and SDMMC_CLKSRC registers, as required. Set the start_cmd, Update_clk_regs_only, and wait_prvdata_complete bits in the SDMMC_CMD register. Wait until start_cmd is cleared or an HLE is set; in case of an HLE, repeat the command.

Re-enable all clocks by programming the SDMMC_CLKENA register. Set the start_cmd, update_clk_regs_only, and wait_prvdata_complete bits in the SDMMC_CMD register. Wait until start_cmd is cleared or an HLE is set; in case of an HLE, repeat the command.

39.6.2.4 No-Data Command With or Without Response Sequence

To send any non-data command, the software needs to program the SDMMC_CMD register @0x2C and the SDMMC_CMDARG register @0x28 with appropriate parameters. Using these two registers, the Host Controller forms the command and sends it to the command bus. The Host Controller reflects the errors in the command response through the error bits of the SDMMC_RINTSTS register.

When a response is received – either erroneous or valid – the Host Controller sets the command_done bit in the SDMMC_RINTSTS register. A short response is copied in Response Register0, while along response is copied to all four response registers @0x30, 0x34, 0x38, and 0x3C. The Response3 register bit 31 represents the MSB, and the Response0 register bit 0 represents the LSB of a long response.

For basic commands or non-data commands, follow these steps:

1) Program the Command register @0x28 with the appropriate command argument parameter.
2) Program the Command register @0x2C with the settings in following table.

Table 39-10 Command Settings for No-Data Command

Parameter	Value	Description
Default		
start_cmd	1	-
use_hold_reg	1	Choose value based on speed mode being used; ref to "use_hold_reg" on SDMMC_CMD register
update_clk_regs_only	0	No clock parameters update command
data_expected	0	No data command
card number	0	Actual card number(one controller only connect one card, the num is No. 0)
cmd_index	command-index	-
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
response_length	0	Can be 1 for R2(long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
wait_prvdata_complete	1	Before sending command on command line, host should wait for completion of any

Rockchip Confidential

Parameter	Value	Description
		data command in process, if any (recommended to always set this bit, unless the current command is to query status or stop data transfer when transfer is in progress)
check_response_crc	1	If host should crosscheck CRC of response received

3) Wait for command acceptance by host. The following happens when the command is loaded into the Host Controller:

- Host Controller accepts the command for execution and clears the start_cmd bit in the SDMMC_CMD register, unless one command is in process, at which point the Host Controller can load and keep the second command in the buffer.
- If the Host Controller is unable to load the command – that is, a command is already in progress, a second command is in the buffer, and a third command is attempted – then it generates an HLE (hardware-locked error).

4) Check if there is an HLE.
5) Wait for command execution to complete. After receiving either a response from a card or response timeout, the Host Controller sets the command_done bit in the SDMMC_RINTSTS register. Software can either poll for this bit or respond to a generated interrupt.
6) Check if response_timeout error, response_CRC error, or response error is set. This can be done either by responding to an interrupt raised by these errors or by polling bits 1, 6, and 8 from the SDMMC_RINTSTS register @0x44. If no response error is received, then the response is valid. If required, the software can copy the response from the response registers @0x30-0x3C.

Software should not modify clock parameters while a command is being executed.

39.6.2.5 Data Transfer Commands

Data transfer commands transfer data between the memory card and the Host Controller. To send a data command, the Host Controller needs a command argument, total data size, and block size. Software can receive or send data through the FIFO.

Before a data transfer command, software should confirm that the card is not busy and is in a transfer state, which can be done using the CMD13 and CMD7 commands, respectively. For the data transfer commands, it is important that the same bus width that is programmed in the card should be set in the card type register @0x18.

The Host Controller generates an interrupt for different conditions during data transfer, which are reflected in the SDMMC_RINTSTS register @0x44 as:

1) Data_Transfer_Over (bit 3) – When data transfer is over or terminated. If there is a response timeout error, then the Host Controller does not attempt any data transfer and the "Data Transfer Over" bit is never set.
2) Transmit_FIFO_Data_request (bit 4) – FIFO threshold for transmitting data was reached; software is expected to write data, if available, in FIFO.
3) Receive_FIFO_Data_request (bit 5) – FIFO threshold for receiving data was reached; software is expected to read data from FIFO.
4) Data starvation by Host timeout (bit 10) – FIFO is empty during transmission or is full during reception. Unless software writes data for empty condition or reads data for full condition, the Host Controller cannot continue with data transfer. The clock to the card has been stopped.
5) Data read timeout error (bit 9) – Card has not sent data within the timeout period.
6) Data CRC error (bit 7) – CRC error occurred during data reception.
7) Start bit error (bit 13) – Start bit was not received during data reception.
8) End bit error (bit 15) – End bit was not received during data reception or for a write operation; a CRC error is indicated by the card.

Conditions 6), 7), and 8) indicate that the received data may have errors. If there was a response timeout, then no data transfer occurred.

Rockchip Confidential

39.6.2.6 Single-Block or Multiple-Block Read

Steps involved in a single-block or multiple-block read are:

1) Write the data size in bytes in the SDMMC_BYTCNT register @0x20.
2) Write the block size in bytes in the SDMMC_BLKSIZ register @0x1C. The Host Controller expects data from the card in blocks of size SDMMC_BLKSIZ each.
3) Program the SDMMC_CMDARG register @0x28 with the data address of the beginning of a data read.
4) Program the Command register with the parameters listed in following table. For SD and MMC cards, use CMD17 for a single-block read and CMD18 for a multiple-block read. For SDIO cards, use CMD53 for both single-block and multiple-block transfers.

Table 39-11 Command Setting for Single or Multiple-Block Read

Parameter	Value	Description
Default		
start_cmd	1	-
use_hold_reg	1	Choose value based on speed mode being used; ref to "use_hold_reg" on SDMMC_CMD register
update_clk_regs_only	0	No clock parameters update command
card number	0	Actual card number(one controller only connect one card, the num is No.0)
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
send_auto_stop	0/1	-
transfer_mode	0	Block transfer
read_write	0	Read from card
data_expected	1	Data command
response_length	0	Can be 1 for R2(long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
cmd_index	command-index	-
wait_prvdata_complete	1	0: Sends command immediately 1: Sends command after previous data transfer ends
check_response_crc	1	0: Host Controller should not check response CRC 1: Host Controller should check response CRC

After writing to the SDMMC_CMD register, the Host Controller starts executing the command; when the command is sent to the bus, the command_done interrupt is generated.

- Software should look for data error interrupts; that is, bits 7, 9, 13, and 15 of the SDMMC_RINTSTS register. If required, software can terminate the data transfer by sending a STOP command.
- Software should look for Receive_FIFO_Data_request and/or data starvation by host

Rockchip Confidential

timeout conditions. In both cases, the software should read data from the FIFO and make space in the FIFO for receiving more data.

When a Data_Transfer_Over interrupt is received, the software should read the remaining data from the FIFO.

39.6.2.7 Single-Block or Multiple-Block Write

Steps involved in a single-block or multiple-block write are:

1) Write the data size in bytes in the SDMMC_BYTCNT register @0x20.
2) Write the block size in bytes in the SDMMC_BLKSIZ register @0x1C; the Host Controller sends data in blocks of size SDMMC_BLKSIZ each.
3) Program SDMMC_CMDARG register @0x28 with the data address to which data should be written.
4) Write data in the FIFO; it is usually best to start filling data the full depth of the FIFO.
5) Program the Command register with the parameters listed in following table.

Table 39-12 Command Settings for Single or Multiple-Block Write

Parameter	Value	Description
Default		
start_cmd	1	-
use_hold_reg	1	Choose value based on speed mode being used; ref to "use_hold_reg" on SDMMC_CMD register
update_clk_regs_only	0	No clock parameters update command
card number	0	Actual card number(one controller only connect one card, the num is No. 0)
send_initialization	0	Can be 1, but only for card reset commands, such as CMD0
stop_abort_cmd	0	Can be 1 for commands to stop data transfer, such as CMD12
send_auto_stop	0/1	-
transfer_mode	0	Block transfer
read_write	1	Write to card
data_expected	1	Data command
response_length	0	Can be 1 for R2(long) response
response_expect	1	Can be 0 for commands with no response; for example, CMD0, CMD4, CMD15, and so on
User-selectable		
cmd_index	command-index	-
wait_prvdata_complete	1	0: Sends command immediately 1: Sends command after previous data transfer ends
check_response_crc	1	0: Host Controller should not check response CRC 1: Host Controller should check response CRC

After writing to the SDMMC_CMD register, Host Controller starts executing a command; when the command is sent to the bus, a command_done interrupt is generated.

- Software should look for data error interrupts; that is, for bits 7, 9, and 15 of the SDMMC_RINTSTS register. If required, software can terminate the data transfer by

Rockchip Confidential

sending the STOP command.
- Software should look for Transmit_FIFO_Data_Request and/or timeout conditions from data starvation by the host. In both cases, the software should write data into the FIFO.

When a Data_Transfer_Over interrupt is received, the data command is over. For an open-ended block transfer, if the byte count is 0, the software must send the STOP command. If the byte count is not 0, then upon completion of a transfer of a given number of bytes, the Host Controller should send the STOP command, if necessary. Completion of the AUTO-STOP command is reflected by the Auto_command_done interrupt – bit 14 of the SDMMC_RINTSTS register. A response to AUTO_STOP is stored in SDMMC_RESP1 @0x34.

39.6.2.8 Sending Stop or Abort in Middle of Transfer

The STOP command can terminate a data transfer between a memory card and the Controller, while the ABORT command can terminate an I/O data transfer for only the SDIO_IOONLY and SDIO_COMBO cards.
- Send STOP command – Can be sent on the command line while a data transfer is in progress; this command can be sent at any time during a data transfer.

You can also use an additional setting for this command in order to set the Command register bits (5-0) to CMD12 and set bit 14 (stop_abort_cmd) to 1. If stop_abort_cmd is not set to 1, the Controller does not know that the user stopped a data transfer. Reset bit 13 of the Command register (wait_prvdata_complete) to 0 in order to make the Controller send the command at once, even though there is a data transfer in progress.
Send ABORT command – Can be used with only an SDIO_IOONLY or SDIO_COMBO card. To abort the function that is transferring data, program the function number in ASx bits (CCCR register of card, address 0x06, bits (0-2) using CMD52.

39.6.2.9 Read_Wait Sequence

Read_wait is used with only the SDIO card and can temporarily stall the data transfer—either from function or memory—and allow the host to send commands to any function within the SDIO device. The host can stall this transfer for as long as required. The Host Controller provides the facility to signal this stall transfer to the card. The steps for doing this are:

1) Check if the card supports the read_wait facility; read SRW (bit 2) of the CCCR register @0x08. If this bit is 1, then all functions in the card support the read_wait facility. Use CMD52 to read this bit.
2) If the card supports the read_wait signal, then assert it by setting the read_wait (bit 6) in the SDMMC_CTRL register @0x00.

Clear the read_wait bit in the SDMMC_CTRL register.

39.6.2.10 Controller/DMA/FIFO Reset Usage

- Controller reset – Resets the controller by setting the controller_reset bit (bit 0) in the SDMMC_CTRL register; this resets the CIU and state machines, and also resets the BIU-to-CIU interface. Since this reset bit is self-clearing, after issuing the reset, wait until this bit is cleared.
- FIFO reset - Resets the FIFO by setting the fifo_reset bit (bit 1) in the SDMMC_CTRL register; this resets the FIFO pointers and counters of the FIFO. Since this reset bit is self-clearing, after issuing the reset, wait until this bit is cleared.

In external DMA transfer mode, even when the FIFO pointers are reset, if there is a DMA transfer in progress, it could push or pop data to or from the FIFO; the DMA itself completes correctly. In order to clear the FIFO, the software should issue an additional FIFO reset and clear any FIFO under-run or overrun errors in the SDMMC_RAWINTS register caused by the DMA transfers after the FIFO was reset.

39.6.2.11 Card Read Threshold

When an application needs to perform a Single or Multiple Block Read command, the application must program the SDMMC_CARDTHRCTL register with the appropriate Card Read Threshold size (CardRdThreshold) and set the Card Read Threshold Enable

Rockchip Confidential

(CardRdThrEnable) bit to 1'b1. This additional programming ensures that the Host controller sends a Read Command only if there is space equal to the Card Read Threshold available in the Rx FIFO. This in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. The Card Read Threshold can be set to the block size of the transfer, which guarantees that there is a minimum of one block size of space in the RxFIFO before the controller enables the card clock. The Card Read Threshold is required when the Round Trip Delay is greater than 0.5cclk_in period.

39.6.2.12 Error Handling

The Host Controller implements error checking; errors are reflected in the SDMMC_RAWINTS register@0x44 and can be communicated to the software through an interrupt, or the software can poll for these bits. Upon power-on, interrupts are disabled (int_enable in the SDMMC_CTRL register is 0), and all the interrupts are masked (bits 0-31 of the SDMMC_INTMASK register; default is 0).
Error handling:

- Response and data timeout errors – For response timeout, software can retry the command. For data timeout, the Host Controller has not received the data start bit – either for the first block or the intermediate block – within the timeout period, so software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the SDMMC_TCBCNT later, the software can decide how many bytes remain to be copied.
- Response errors – Set when an error is received during response reception. In this case, the response that copied in the response registers is invalid. Software can retry the command.
- Data errors – Set when error in data reception are observed; for example, data CRC, start bit not found, end bit not found, and so on. These errors could be set for any block-first block, intermediate block, or last block. On receipt of an error, the software can issue a STOP or ABORT command and retry the command for either whole data or partial data.
- Hardware locked error – Set when the Host Controller cannot load a command issued by software. When software sets the start_cmd bit in the SDMMC_CMD register, the Host Controller tries to load the command. If the command buffer is already filled with a command, this error is raised. The software then has to reload the command.
- FIFO under-run/overrun error – If the FIFO is full and software tries to write data in the FIFO, then an overrun error is set. Conversely, if the FIFO is empty and the software tries to read data from the FIFO, an under-run error is set. Before reading or writing data in the FIFO, the software should read the fifo_empty or fifo_full bits in the Status register.
- Data starvation by host timeout – Raised when the Host Controller is waiting for software intervention to transfer the data to or from the FIFO, but the software does not transfer within the stipulated timeout period. Under this condition and when a read transfer is in process, the software should read data from the FIFO and create space for further data reception. When a transmit operation is in process, the software should fill data in the FIFO in order to start transferring data to the card.
- CRC Error on Command – If a CRC error is detected for a command, the CE-ATA device does not send a response, and a response timeout is expected from the Host Controller. The ATA layer is notified that an MMC transport layer error occurred.

Notes: During a multiple-block data transfer, if a negative CRC status is received from the device, the data path signals a data CRC error to the BIU by setting the data CRC error bit in the SDMMC_RINTSTS register. It then continues further data transmission until all the bytes are transmitted.

39.6.2.13 Voltage Switching

The Host Controller supports SD 3.0 Ultra High Speed (UHS-1) and is capable of voltage switching in SD-mode, which can be applied to SD High-Capacity (SDHC) and SD Extended Capacity (SDXC) cards. UHS-1 supports only 4-bit mode.
However, whether the IO voltage of 1.8v supported or not is depended on the SoC design.
SD 3.0 UHS-1 supports the following transfer speed modes for UHS-50 and/or UHS-104 cards:

Rockchip Confidential

- DS – default-speed up to 25MHz, 3.3V signaling
- HS – high-speed up to 50MHz, 3.3V signaling
- SDR12 – SDR up to SDR 25MHz, 1.8V signaling
- SDR25 – SDR up to 50MHz, 1.8V signaling
- SDR50 – SDR up to 100MHz, 1.8V signaling
- DDR50 – DDR up to 50MHz, 1.8V signaling

Voltage selection can be done in only SD mode. The first CMD0 selects the bus mode-either SD mode or SPI mode. The card must be in SD mode in order for 1.8V signaling mode to apply, during which time the card cannot be switched to SPI mode or 3.3V signaling without a power cycle.

If the System BIOS in an embedded system already knows that it is connected to an SD 3.0 card, then the driver programs the Controller to initiate ACMD41. The software knows from the response of ACMD41 whether or not the card supports voltage switching to 1.8V.

- If bit 32 of ACMD41 response is 1'b1: card supports voltage switching and next command-CMD11-invokes voltage switching sequence. After CMD11 is started, the software must program the IO voltage selection register based on the soc architecture.
- If bit 32 of ACMD41 response is 1'b0: card does not support voltage switching and CMD11 should not be started.

If the card and host controller accept voltage switching, then they support UHS-1 modes of data transfer. After the voltage switch to 1.8V, SDR12 is the default speed.

Since the UHS-1 can be used in only 4-bit mode, the software must start ACMD6 and change the card data width to 4-bit mode; ACMD6 is driven in any of the UHS-1 speeds. If the host wants to select the DDR mode of data transfer, then the software must program the SDMMC_DDR_REG register in the CSR space with the appropriate card number.

To choose from any of the SDR or DDR modes, appropriate values should be programmed in the SDMMC_CLKDIV register.

39.6.2.14 Voltage Switch Operation

The Voltage Switch operation must be performed in SD mode only.

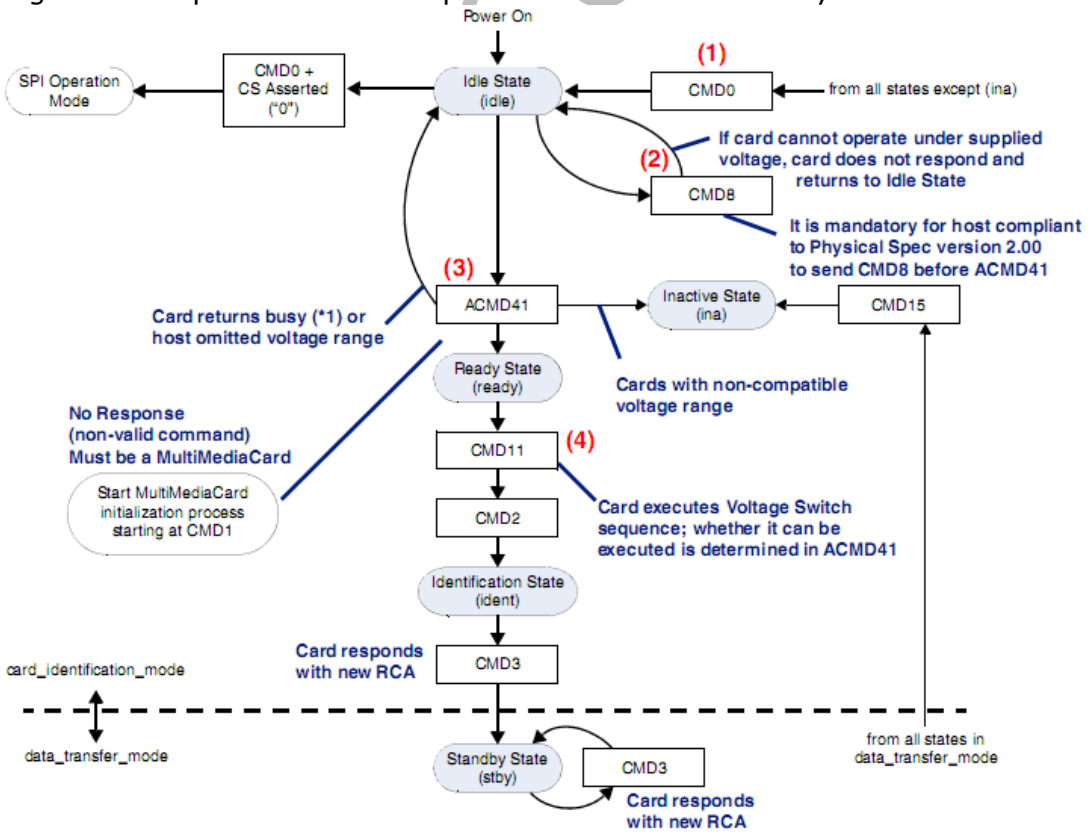

Fig. 39-10 Voltage Switching Command Flow Diagram

The following outlines the steps for the voltage switch programming sequence

1) Software Driver starts CMD0, which selects the bus mode as SD.
2) After the bus is in SD card mode, CMD8 is started in order to verify if the card is

Rockchip Confidential

compatible with the SD Memory Card Specification, Version 2. 00. CMD8 determines if the card is capable of working within the host supply voltage specified in the VHS (19:16) field of the CMD; the card supports the current host voltage if a response to CMD8 is received.

3) ACMD 41 is started. The response to this command informs the software if the card supports voltage switching; bits 38, 36, and 32 are checked by the card argument of ACMD41; refer to following figure.

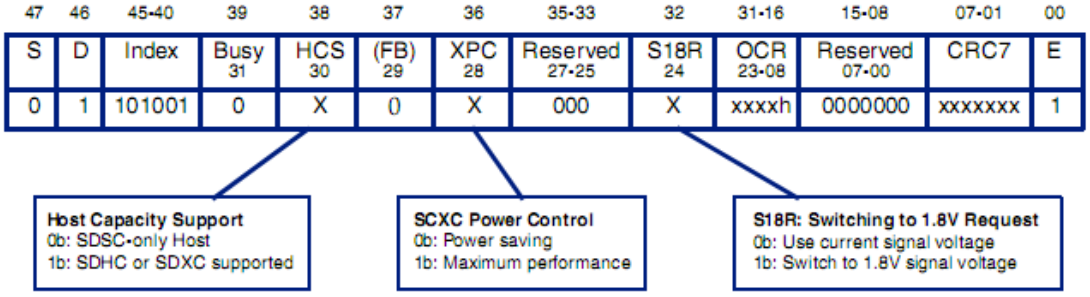

Fig. 39-11 ACMD41 Argument

- Bit 30 informs the card if host supports SDHC/SDXC or not; this bit should be set to 1'b1.
- Bit 28 can be either 1 or 0.
- Bit 24 should be set to 1'b1, indicating that the host is capable of voltage switching; refer to following figure.

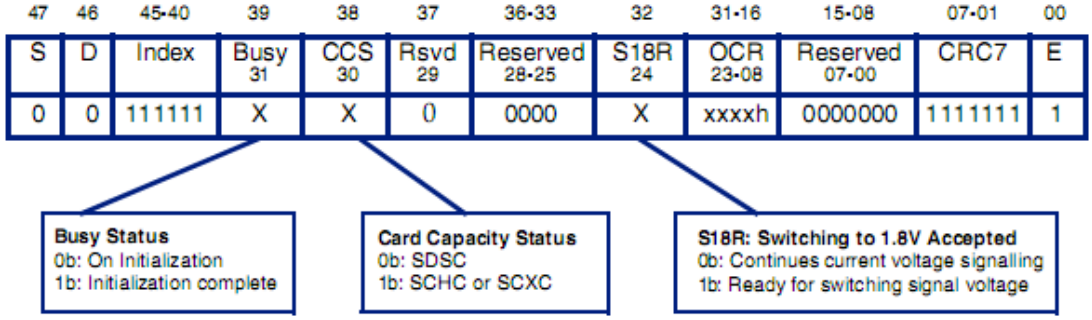

Fig. 39-12 ACMD41 Response(R3)

- Bit 30 – If set to 1'b1, card supports SDHC/SDXC; if set to 1'b0, card supports only SDSC
- Bit 24 – If set to 1'b1, card supports voltage switching and is ready for the switch
- Bit 31 – If set to 1'b1, initialization is over; if set to 1'b0, means initialization in process

If the card supports voltage switching, then the software must perform the steps discussed for either the "Voltage Switch Normal Scenario" or the "Voltage Switch Error Scenario".

Rockchip Confidential

39.6.2.15 Voltage Switch Normal Scenario

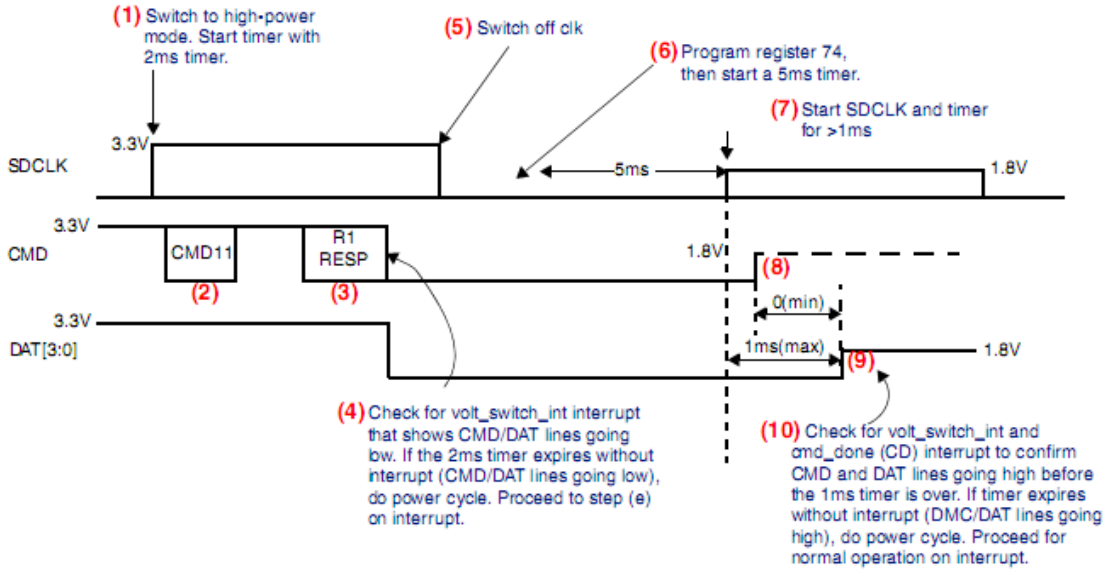

Fig. 39-13 Voltage Switch Normal Scenario

1) The host programs SDMMC_CLKENA—cclk_low_power register—with zero (0) for the corresponding card, which makes the host controller move to high-power mode. The application should start a timer with a recommended value of 2ms; this value of 2ms is determined as below: Total cycles required for CMD11 = 48 cycles
   Total cycles required for RESP R1 = 48 cycles
   Maximum clock delay between MCD11 end to start of RESP1 = 60 cycles
   Total = 48+48 + 60 = 160
   Minimum frequency during enumeration is 100KHz; that is, 10us
   Total time = 160 * 10us = 1600us = 1. 6ms ~ 2ms
2) The host issues CMD11 to start the voltage switch sequence. Set bit 28 to 1'b1 in CMD when setting CMD11; for more information on setting bits, refer to “Boot Operation”.
3) The card returns R1 response; the host controller does not generate cmd_done interrupt on receiving R1 response.
4) The card drives CMD and DAT [3:0] to low immediately after the response. The host controller generates interrupt (VOLT_SWITCH_INT) once the CMD or DAT [3:0] line goes low. The application should wait for this interrupt. If the 2ms timer expires without an interrupt (CMD/DAT lines going low), do a power cycle.

Note: Before doing a power cycle, switch off the card clock by programming SDMMC_CLKENA register

Proceed to step (5) on getting an interrupt (VOLT_SWITCH_INT).

Note: This interrupt must be cleared once this interrupt is received. Additionally, this interrupt should not be masked during the voltage switch sequence.

If the timer expires without interrupt (CMD/DAT lines going low), perform a power cycle. Proceed to step (5) on interrupt.

1) Program the SDMMC_CLKENA register, with 0 for the corresponding card; the host stops supplying SDCLK.
2) Program Voltage register to the required values for the corresponding card. The application should start a timer > 5ms.
3) After the 5ms timer expires, the host voltage regulator is stable. Program SDMMC_CLKENA register, with 1 for the corresponding card; the host starts providing SDCLK at 1. 8V; this can be at zero time after Voltage register has been programmed. When the SDMMC_CLKENA register is programmed, the application should start another timer > 1ms.
4) By detecting SDCLK, the card drives CMD to high at 1. 8V for at least one clock and then stops driving (tri-state); CMD is triggered by the rising edge of SDCLK (SDR timing).
5) If switching to 1. 8V signaling is completed successfully, the card drives DAT [3:0] to high at 1. 8V for at least one clock and then stops driving (tri-state); DAT [3:0] is triggered by the rising edge of SDCLK (SDR timing). DAT[3:0] must be high within 1ms

Rockchip Confidential

from the start of SDCLK.

6) The host controller generates a voltage switch interrupt (VOLT_SWITCH_INT) and a command done (CD) interrupt once the CMD and DAT[3:0] lines go high. The application should wait for this interrupt to confirm CMD and DAT lines going high before the 1ms timer is done.

If the timer expires without the voltage switch interrupt (VOLT_SWITCH_INT), a power cycle should be performed. Program the SDMMC_CLKENA register to stop the clock for the corresponding card number. Wait for the cmd_done (CD) interrupt. Proceed for normal operation on interrupt. After the sequence is completed, the host and the card start communication in SDR12 timing.

39.6.2.16 Voltage Switch Error Scenario

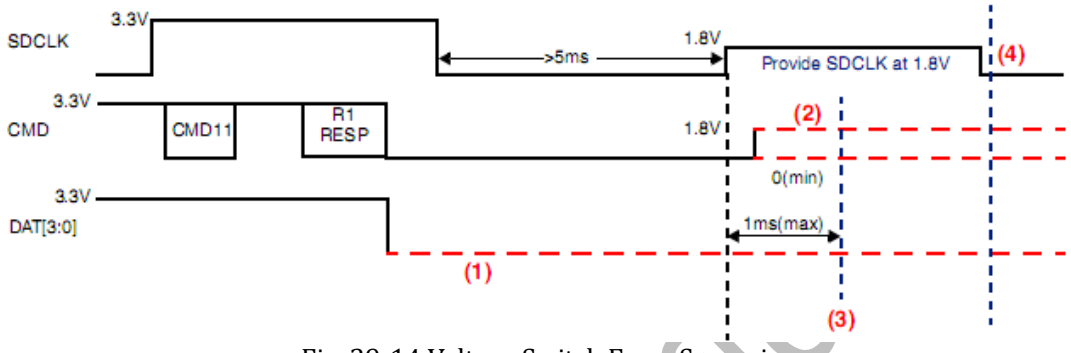

Fig. 39-14 Voltage Switch Error Scenario

1) If the interrupt (VOLT_SWITCH_INT) does not come, then the 2ms timer should time out and a power cycle should be initiated.

Note: Before performing a power cycle, switch off the card clock by programming SDMMC_CLKENA register; no cmd_done (CD) interrupt is generated.

Additionally, if the card detects a voltage error at any point in between steps (5) and (7) in the card keeps driving DAT[3:0] to low until card power off.

2) CMD can be low or tri-state.
3) The host controller generates a voltage switch interrupt once the CMD and DAT[3:0] lines go high. The application should check for an interrupt to confirm CMD and DAT lines going high before the 1 ms timer is done.

If the 1 ms timer expires without interrupt (VOLT_SWITCH_INT) and cmd_done (CD), a power cycle should be performed. Program the SDMMC_CLKENA register to stop SDCLK of the corresponding card. Wait for the cmd_done interrupt. Proceed for normal operation on interrupt.

4) If DAT[3:0] is low, the host drives SDCLK to low and then stops supplying the card power.

Note: The card checks voltages of its own regulator output and host signals to ensure they are less than 2. 5V. Errors are indicated by (1) and (2).

- If voltage switching is accepted by the card, the default speed is SDR12.
- Command Done is given:
  - If voltage switching is properly done, CMD and DAT line goes high.
  - If switching is not complete, the 1ms timer expires, and the card clock is switched off.

Note: No other CMD should be driven before the voltage switching operation is completed and Command Done is received.

- The application should use CMD6 to check and select the particular function; the function appropriate-speed should be selected.

After the function switches, the application should program the correct value in the CLKDIV register, depending on the function chosen. Additionally, if Function 0x4 of the Access mode is chosen—that is, DDR50, then the application should also program 1'b1 in DDR_REG for the card number that has been selected for DDR50 mode.

39.6.3 DDR Operation

39.6.3.1 4-bit DDR Programming Sequence

DDR programming should be done only after the voltage switch operation has completed. The following outlines the steps for the DDR programming sequence:

Rockchip Confidential

1) Once the voltage switch operation is complete, the user must program voltage selection register to the required values for the corresponding card.

- To start a card to work in DDR mode, the application must program a bit of the newly defined SDMMC_UHSREG[16] register with a value of 1'b1.
- The bit that the user programs depends on which card is to be accessed in DDR mode.

To move back to SDR mode, a power cycle should be run on the card—putting the card in SDR12 mode—and only then should SDMMC_UHSREG[16]be set back to 1'b0 for the appropriate card.

39.6.3.2 eMMC4.5 DDR START Bit

The eMMC4.5 changes the START bit definition in the following manner:

1) Receiver samples the START bit on the rising edge.
2) On the next rising edge after sampling the START bit, the receiver must sample the data.
3) Removes requirement of the START bit and END bit to be high for one full cycle.

Notes: The Host Controller does not support a START bit duration higher than one clock cycle. START bit durations of one or less than one clock cycle are supported and can be defined at the time of startup by programming the EMMC_DDR_REG register.

39.6.3.3 Reset Command/Moving From DDR50 to SDR12

To reset the mode of operation from DDR50 to SDR12, the following sequence of operations has to be done by the application:

1) Issue CMD0.
2) When CMD0 is received, the card changes from DDR50 to SDR12.
3) Program the SDMMC_CLKDIV register with an appropriate value.
4) Set ddr_reg to 0.

Note: The Voltage register should not be programmed to 0 while switching from DDR50 to SDR12, since the card is still operating in 1.8V mode after receiving CMD0.

39.6.4 H/W Reset Operation

When the RST_n signal goes low, the card enters a pre-idle state from any state other than the inactive state.

The following outlines the steps for the H/W reset programming sequence:

1) Program CMD12 to end any transfer in process.
2) Wait for DTO, even if no response is sent back by the card.
3) Set the following resets:

- DMA reset–SDMMC_CTRL [2] bit
- FIFO reset–SDMMC_CTRL [1] bit

Note: The above steps are required only if a transfer is in process.

4) Program the SDMMC_RSTN register with a value of 0; this can be done at any time when the card is connected to the controller. This programming asserts the RST_n signal and resets the card.
5) Wait for minimum of 1 µs or cclk_in period, whichever is greater
6) After a minimum of 1 µs, the application should program a value of 0 into the SDMMC_RSTN register. This de-asserts the RST_n signal and takes the card out of reset.
7) The application can program a new CMD only after a minimum of 200µs after the de-assertion of the RST_n signal, as per the MMC 4.41 standard.

Note: For backward compatibility, the RST_n signal is temporarily disabled in the card by default. The host may need to set the signal as either permanently enabled or permanently disabled before it uses the card.

39.6.5 FBE Scenarios

An FBE occurs due to an AHB error response on the AHB bus. This is a system error, so the software driver should not perform any further programming to the Host. The only recovery mechanism from such scenarios is to do one of the following:

- Issue a hard reset by asserting the reset_n signal
- Do a program controller reset by writing to the SDMMC_CTRL[0] bit

Rockchip Confidential

39.6.5.1 FIFO Overflow and Underflow

During normal data transfer conditions, FIFO overflow and underflow will not occur. However if there is a programming error, then FIFO overflow/underflow can result. For example, consider the following scenarios.

- For transmit: PBL=4, Tx watermark = 1. For the above programming values, if the FIFO has only one location empty, it issues a dma_req to IDMAC FSM. Due to PBL value=4, the IDMAC FSM performs 4 pushes into the FIFO. This will result in a FIFO overflow interrupt.
- For receive: PBL=4, Rx watermark = 1. For the above programming values, if the FIFO has only one location filled, it issues a dma_req to IDMAC FSM. Due to PBL value=4, the IDMAC FSM performs 4 pops to the FIFO. This will result in a FIFO underflow interrupt.

The driver should ensure that the number of bytes to be transferred as indicated in the descriptor should be a multiple of 4bytes with respect to H_DATA_WIDTH=32. For example, if the SDMMC_BYTCNT=13, the number of bytes indicated in the descriptor should be 16 for H_DATA_WIDTH=32.

39.6.5.2 Programming of PBL and Watermark Levels

The DMAC performs data transfers depending on the programmed PBL and threshold values.

Table 39-13 PBL and Watermark Levels

PBL (Number of transfers)	Tx/Rx Watermark Value
1	Greater than or equal to 1
4	Greater than or equal to 4
8	Greater than or equal to 8
16	Greater than or equal to 16
32	Greater than or equal to 32
64	Greater than or equal to 64
128	Greater than or equal to 128
256	Greater than or equal to 256

39.6.6 Variable Delay Usage

The control signals for variable delay element usage are described in SDMMC_CLKGEN_CON0 and SDMMC_CLKGEN_CON1.

The following outlines the steps for clock generation sequence:

1) Assert init_state to soft reset the CLKGEN.
2) Configure drv_degree/sample_degree.
3) If fine adjustment required, delay line can be used by configuring drv_delaynum/sample_delaynum and drv_sel/sample_sel.
4) Dis-assert init_state to start CLKGEN.

39.6.7 Variable Delay Tuning

Tuning is defined by SD and MMC cards to determine the correct sampling point required for the host, especially for the speed modes SDR104 and HS200 where the output delays from the cards can be up to 2 UI. Tuning is required for other speed modes-such as DDR50-even though the output delay from the card is less than one cycle.

Command for tuning is different for different cards.

- SD Memory Card:
  - CMD19 – SD card for SDR50 and SDR104 speed modes. Tuning data is defined by card specifications.
  - CMD6 – SD card for speed modes not supporting CMD19. Tuning data is the 64byte SD status.
- Multimedia Card:
  - CMD21 – MMC card for HS200 speed mode. Tuning data is defined by card specifications.
  - CMD8 – MMC card for speed modes not supporting CMD21. Tuning data is 512 byte ExtCSD data.

Rockchip Confidential

The following is the procedure for variable delay tuning:

1) Set a phase shift of 0-degree on cclk_in_sample.
2) Send the Tuning command to the card; the card in turn sends an R1 response on the CMD line and tuning data on the DAT line.
3) If the host sees any of the errors—start bit error, data CRC error, end bit error, data read time-out, response CRC error, response error—then the sampling point is incorrect.
4) Send CMD12 to bring the host controller state machines to idle.
   - The card may treat CMD12 as an invalid command because the card has successfully sent the tuning data, and it cannot send a response.
   - The host controller may generate a response time-out interrupt that must be cleared by software.
5) Repeat steps 2) to 4) by increasing the phase shift value or delay element number on cclk_in_sample until the correct sampling point is received such that the host does not see any of the errors.
6) Mark this phase shift value as the starting point of the sampling window.
7) Repeat steps 2 to 4 by increasing the phase shift value or delay element number on cclk_in_sample until the host sees the errors starting to come again or the phase shift value reaches 360-degree.
8) Mark the last successful phase shift value as the ending point of the sampling window.

A window is established where the tuning block is matched. For example, for a scenario where the tuning block is received correctly for a phase shift window of 90-degree and 180-degree, then an appropriate sampling point is established as 135-degree. Once a sampling point is established, no errors should be visible in the tuning block.
